Crime, Unemployment and

Kangoh Lee

Department of Economics, San Diego State University, San Diego, CA, USA

Definition

Crime is one of the most important social issues citizens are concerned about. As such, it has received a good deal of attention from policymakers and scholars across fields such as criminology, economics, law, psychology, and sociology. Crime is partly motivated by economic conditions, and a large body of research has studied the relationship between economic factors, particularly unemployment, and crime for more than 50 years. Available evidence shows that the relationship is ambiguous, and it is an actively researched topic.

Introduction

Crime was first analyzed by economists in the late 1960s and early 1970s (e.g., Becker 1968; Ehrlich 1973). The analysis is based on the cost and benefit of crime. The cost to an individual who commits property crime is the lost legitimate incomes and the penalties when crime is caught, and the stolen properties and incomes constitute the benefit (see Anderson 2017 for a general discussion of the cost). The individual then compares the cost and the benefit when deciding to commit crime.

Applying the cost-benefit analysis of crime to the relationship between unemployment and crime, an increase in unemployment during economic downturns should increase crime, as the increase in unemployment decreases the cost of crime, namely, the lost legitimate income. However, this seemingly obvious and intuitive prediction has not been empirically supported. Rather, empirical findings have been mixed, ranging from positive effects of unemployment on crime to no stable or statistically significant effect and to negative effects. The relationship between

unemployment and crime is thus intriguing and one of the most controversial topics in law and economics. At the same time, this discrepancy between economic theory and empirical findings indicates that the unemployment-crime nexus is more complicated than the standard economic theory of crime predicts and calls for more research.

Effects of Unemployment on Crime

Overview

Fleisher (1963) is the first study to examine the effect of unemployment on crime. Based on data for property crimes from FBI Uniform Crime Reports over the period 1932–1961 across Boston, Chicago, and Cincinnati, he finds that the elasticity of the arrest rates with respect to the unemployment rate of young males is between 0.10 and 0.25. Since his work, a large number of research papers have empirically studied the relationship between labor market conditions and crime. These studies typically utilize panel data across jurisdictions such as counties or states during a certain period of time. They typically use instrumental-variable approaches to take into account the possible endogeneity of unemployment and to correct for simultaneity between unemployment and crime and controls for other covariates such as ages, incomes, police expenditures, and metropolitan areas (e.g., Raphael and Winter-Ebmer 2001; Gould et al. 2002; Lin 2008).

The literature on the topic has significantly grown, and a good number of papers have reviewed this growing literature (Long and Witte 1981; Freeman 1983, 1995; Chiricos 1987; Levitt 2004; Blumstein and Wallman 2006). These reviews show that the effects of unemployment on crime are positive, and sometimes statistically insignificant, and sometimes even negative. For instance, Freeman (1983) reviews 15 empirical studies and finds that unemployment has positive and significant effects on crime only in four studies. Chiricos (1987), by contrast, finds that unemployment has significant positive effects on crime in a majority of 63 studies he reviews.

These diverse findings show that the relationship between unemployment and crime is complicated. At the same time, these findings reflect the possibility that the relationship also hinges on the types of crimes and the characteristics of those individuals who commit crime. Crimes of passion such as murder and rape would depend less on economic conditions than crimes driven by economic incentives such as burglary and other types of property crimes. The youths have fewer economic opportunities than adults, and their motivation to commit crime may differ from adults'. Social customs and cultures that may govern the incentives to commit crime play a role in shaping the relationship. It is thus useful to examine the relationship between unemployment and crime separately for different types of crimes, for different groups of individuals, and for different countries.

Types of Crimes

There are different ways of categorizing crimes, but for the purpose of this entry, two types of crimes, violent crimes and property crimes, are relevant. According to the FBI Uniform Reporting Program, violent crimes are the offenses involving force or threat of force and consist of murder, rape, robbery, and aggravated assault. Property crimes do not involve force or threat of force against the victims and include burglary, larceny, motor vehicle theft, and arson.

The standard economics argument dictates that an increase in the unemployment rate in general should increase property crime but may not have much effect on violent crime. The reason is that those who commit property crime are interested in the properties of the victims rather than the victims themselves, and the economic conditions of the offenders such as their wages and employment status and those of the properties such as their market values affect the incentives to commit property crime. By contrast, violent crimes are the offenses against the victims, and the economic conditions of the offenders or the victims would not affect the incentives to commit violent crime in an important manner.

Recent empirical studies have on average confirmed the standard economics argument, but have

found that unemployment does not have uniform effects on property crime or violent crime (Raphael and Winter-Ebmer 2001; Gould et al. 2002; Lin 2008). In particular, an increase in unemployment is on average associated with a significant increase in property crime but has little effect on violent crime. However, an increase in the unemployment rates increases assault and robbery, but decreases murder and rape (Raphael and Winter-Ebmer 2001). In addition, the unemployment rate has a positive and significant effect on burglary and larceny, but a negative and significant effect on auto theft (Gould et al. 2002). Thus, unlike the standard economics argument, an increase in unemployment may affect some types of violent crimes in a significant manner and may decrease rather than increase some types of property crimes.

As these studies show, crimes driven by economic incentives, particularly burglary, appear to be strongly affected by unemployment, but the linkage between unemployment and violent crime is weak. If unemployment has any stable and expected effect on violent crime, it would affect robbery in a predictable manner, because robbery is a violent crime but close to property crime in its nature.

Different Countries

Diverse empirical findings may be attributed to different cultures and social norms, as the decision to commit crime may depend in part on cultures. This section discusses empirical findings across different countries to separate the effect of unemployment from the role of cultures and other social influences in crime. The literature mentioned above focuses on US data, and other countries and cross-country studies are considered below.

A number of studies have examined the link between unemployment and crime in Europe. In Germany, the effect of unemployment differs between before and after reunification. In particular, unemployment has little effect on crime in West Germany but has significant and positive effects on robbery and theft in reunified Germany (Entorf and Spengler 2000). In Sweden, unemployment has the expected effects on crime in the sense that unemployment has a positive and

significant effect on property crime, but no significant effect on violent crime (Edmark 2005). In England and Wales, an increase in unemployment decreases fraud and increases drug and other crimes among ten police-recorded crimes (Wu and Wu 2012).

As for countries other than the USA and European countries, a positive and significant relationship between unemployment and crime has been found in New Zealand (Papps and Winkelmann 2000), in Malaysia (Tang 2011), and in some Latin American cities but not in other Latin American cities (Hojman 2004). As for multi-country studies, Wolpin (1980) explores three-country data, Japan, the UK, and the USA, and demonstrates that unemployment has a positive effect on crime, and Altindag (2012) analyzes a set of European cross-country data and shows that unemployment increases crime.

The above studies show that the unemployment-crime connection has been extensively investigated across countries, reflecting global interests in the topic. At the same time, judging from their findings, it appears that the relationship between unemployment and crime does not crucially depend on countries in the sense that unemployment largely tends to increase property crime.

Groups of Individuals

Youth crime has been an important subject of crime research in general, as youths are more likely to commit crime than adults and face different economic opportunities. A number of studies consider the effect of youth unemployment on youth crime, and the effect appears to differ from the standard results in the literature above. In particular, it has a long-run positive effect on fraud, homicide, and motor vehicle theft but not on other types of crimes in Australia (Narayan and Smyth 2004), and it increases burglary, theft, and robbery, but not violent crime in England and Wales (Carmichael and Ward 2001). In France, the unemployment rates of 15–24-year-olds increase almost all types of crimes, including violent crimes, but the unemployment rates of 25–49-year-olds decrease almost all crimes, again including violent crimes, although the effects of the

unemployment rates of the latter group are not statistically significant (Fougère et al. 2009).

A rare study, based on Florida county-level data, investigates the effects of unemployment on reconviction for black males and for white males separately (Wang et al. 2010). They find that black ex-prisoners released to areas with high black-male unemployment rates are more likely to commit violent crime, but no such effect is found for white counterparts. They also find that white ex-prisoners released to areas with high white-male manufacturing employment rates are less likely to commit violent crime, but no such effect is found for black counterparts. It is interesting to observe that unemployment rates or employment rates of the areas have no effect on the likelihood of ex-prisoners committing property crime.

The effects of youth unemployment on youth crime appear to differ in the sense that youth unemployment also affects youth violent crime at least in France and Australia. Many studies include the proportion of blacks in a county or region or state as a covariate in their regressions, but few studies consider blacks and whites separately, and the study by Wang et al. (2010) shows that significant differences exist between blacks and whites in terms of the effects of unemployment on recidivism. Another group of individuals of interest are females. Females are known to be less likely to commit crime than males, but no research appears to examine the relationship between female unemployment and female crime.

Moderating Factors

Many studies on the relationship between unemployment and crime control for other covariates, as noted above, but the relationship itself depends on moderating variables. For instance, the effect of unemployment on crime hinges on the apprehension rate (Lee 2016). In particular, an increase in the unemployment rate decreases the crime rate at low apprehension rates but increases the crime rate at high apprehension rates, as apprehension affects both the cost of crime and the benefit of crime.

In regression analysis, moderating variables are captured by interaction terms. While interaction terms have been rarely studied in the

literature, Baron (2008) includes an interaction term between youth unemployment and monetary dissatisfaction in the youth violent-crime regression and an interaction term between youth unemployment and job search activities in the youth drug-crime regression. The regression results show that an increase in youth unemployment tends to increase youth violent crimes when youths are more dissatisfied with their monetary situations, and it tends to decrease youth drug crimes when they search for jobs more regularly.

Other Labor Market Conditions and Crime

Among labor market opportunities that may affect crime, unemployment has been the most important determinant of crime. However, other labor market conditions also play an important role in crime. An increase in wages of noncollege-educated or college-educated men reduces crimes broadly, including both property crime and violent crime in the USA (Gould et al. 2002). A decrease in the wages of low-wage workers substantially increases all types of property crime in England and Wales (Machin and Meghir 2004).

Income inequality is another factor that affects crime. The way income inequality affects property crime and violent crime differs significantly from the way unemployment does. More inequality significantly increases violent crime but has no effect on property crime in the USA (Kelly 2000). This finding stands in sharp contrast with the result that unemployment has a positive effect on property crime, but little effect on violent crime. One interpretation of the contrast is that property crime is influenced by economic incentives while violent crime is driven by strain and social situations. The income inequality may affect crime differently in a time-series analysis. In particular, an increase in inequality increases crime rates in the cross-section analysis but decreases crime rates in the time-series analysis (Brush 2007). In a study that relates inequality and unemployment to crime in Latin American cities, Hojman (2004) finds that more inequality significantly increases

crime in Greater Buenos Aires. It is difficult to directly compare Kelly (2000) with the last two studies, as they do not distinguish property crime from violent crime, but income inequality appears to influence crime in general although the inequality-crime nexus has not been extensively studied.

Conclusions

Crime causes private costs to victims and criminals and social costs as well, and policymakers have attempted to reduce crime by spending resources. To the extent that there is a connection between crime and economic incentives, any crime policy has to examine such economic incentives. This entry has focused on unemployment as the key part of economic incentives. Despite a large volume of empirical research on the topic, the literature has not reached a consensus on the effects of unemployment on crime even though the standard economics argument dictates that unemployment must have a positive effect on crime. Rather, the effects depend crucially on the types of crimes and on the characteristics of individuals as well. The literature is still growing and expected to attract attention from scholars and policymakers.

While unemployment is important, other labor market conditions such as wage levels and wage inequality appear to influence the decisions to commit crime. Nevertheless, little research on the wage-crime link or the inequality-crime link has been conducted, and more research on the issue is warranted. In addition, many interesting aspects of crime have been omitted in this entry, but other entries discuss them (e.g., Baker 2017; Leroch 2017; Prescott 2017; Pyne 2017).

Institute of Agricultural and Nutritional Sciences,
Martin Luther University Halle-Wittenberg,
Halle (Saale), Germany

Definition

Economics of crime describes the attempt to explain rule-breaking behaviors based on the assumption that people make purposive choices under conditions of scarcity.

Economics of Crime: Different Paradigms

Economics of crime can be broadly defined as the attempt to explain rule-breaking behaviors based

on the assumption that people make purposive choices under conditions of scarcity. People's choice sets regularly contain both permissible and illicit choices. Illicit choices do not always constitute criminal acts in terms of violations of the criminal law. However, throughout this entry we use crime, illegal behavior, illicit choice, non-compliance, offense, and rule breaking as interchangeable terms for the infringement of formal (codified) rules. **Economics of crime** includes the analysis of **economic crime** and white-collar crime such as corruption, patent infringements, or the violation of industrial safety laws, but it explicitly applies economic approaches to the study of illicit behaviors such as traffic offenses and vandalism, which are often considered being beyond the realm of economics.

Economic approaches share the core understanding that human behaviors are the result of purposive choices – either fully rational (e.g., von Neumann and Morgenstern 1944) or 'intendedly rational' (Simon 1955: 114). However, there is no uniform conception of economic man. Instead, differing models – from purely materialistic and self-interested **rational choice** to multigoal and **bounded-rational choice** – are used to study behaviors in different contexts. This entry systematically discusses competing conceptions (paradigms) of illicit choice.

Beccaria, Bentham, Becker

Gary S. Becker (1968) is one of the most prominent, but by far not the first one to study both crime (self-interested private choice) and crime prevention (welfare-oriented public choice) from an essentially economic (utilitarian) perspective. There are many precursors of Becker in modern history who applied the logic of utilitarian calculus to the study of crime and its **prevention through deterrence**. The most noteworthy one is Beccaria whose famous treatise *Dei delitti e delle pene* (*On Crime and punishment*; 1764/1995) combined utilitarian reasoning with the Enlightenment call for the rule of law and the plea against excessive and disproportionate punishment. Drawing on Hobbes' social contract

theory (1651/2010), Beccaria justified state-imposed punishment as the necessary means to enforce the social contract as codified in the law. Beccaria's ideas on punishment heavily influenced Bentham (1789). Beccaria and Bentham agreed on three fundamentals: (1) the need for legal formalism to justify the justice system, (2) the rejection of capital punishment due to its brutalizing effects on society, and (3) the endorsement of a preventive instead of a retributive rationale in sentencing that limits punishment (Harcourt 2014). Antedating modern-day understanding of deterrence as being both specific and general, Beccaria (1764/1995: 31) detailed that the only purpose of punishment is to "prevent the offender from doing fresh harm to his fellows and to deter others from doing likewise." He also noted that, from a utilitarian point of view, there is a moral-philosophical limitation to punishment: "If a punishment is to serve its purpose, it is enough that the harm of punishment should outweigh the good which the criminal can derive from the crime, [. . .]. Anything more than this is superfluous and, therefore, tyrannous" (Beccaria 1764/1995: 64).

The general idea of **Beccarian deterrence** is that presumptive criminals will respond to the **severity** ("size") of punishment, its **certainty** (probability), and its **celerity** (swiftness). Beccaria and Bentham strongly advocated mild but highly probable and swift punishment. They argued that certainty and swiftness are necessary to make potential criminals realize that crime is closely associated with punishment. In their understanding, the fear of a more severe but less likely and delayed punishment, which inevitably goes hand in hand with the hope of not being captured at all, will deter crime less effectively. They furthermore noted that overly severe penalization might harden criminals and provoke follow-up crimes to avoid capture and hard punishment.

Neoclassical accounts of crime based on twentieth-century microeconomic theory, such as those of the Chicago School of economics and notably Becker (1968), took up the Beccarian idea of utilitarian calculus and deterrence. Becker modeled individuals as materialistic,

self-interested, and rational decision makers who maximize their utility. In line with the **neoclassical paradigm**, Becker supposed people's preferences to be context-independent ("exogenous") and stable. He assumed that individuals calculate and weigh the material benefits (utility) and costs (disutility) of rule breaking and rule abidance without moral considerations. Based on this assumption, Becker arrived at normative regulatory conclusions through the **externality** argument. He contended that the **expectation value of the sanction** ("expected sanction") – as resulting from its size and probability – should be set at a level that makes would-be offenders internalize the negative externalities (harms) they would inflict on the victims. Using the language of price theory, Becker claimed that, to decrease the "supply" of crime, regulators need to engage in monitoring and sanctioning activities (enforcement) to reduce the excessive "price" that criminals could otherwise obtain from illegal activity. Regulators should undertake these law enforcement activities up to the level where their marginal social costs equal the marginal social costs of criminal behavior. This implies tolerating a certain amount of crime because, at some point, the costs of more law enforcement would exceed its benefits.

Becker's normative claim that sanctioning should make offenders internalize the harms inflicted on others was challenged from within the neoclassical camp. Posner (2014) claimed that the expected sanction should prevent crime altogether, by fixing it at a level that (marginally) surpasses the offender's illicit profit. According to Becker's *internalization approach*, one should tolerate "**efficient**" crimes (the breaking of inefficient rules) that lead to a more efficient allocation of resources (Harel 2014). A polluter whose illicit profit exceeds the environmental damage should not be deterred, for example. In contrast to Becker but in line with Beccaria, Posner's *prevention approach* implies that any crime (injury of a legally protected interest) should be prevented by turning it into an inferior option for the agent deliberating it.

Becker focused on "**taxing**" rule breaking as the means to reduce its "price" relative to the one

attached to legal activity. However, as noted by himself, the attractiveness of rule breaking can also be reduced by “**subsidizing**” rule abidance and increasing the opportunity costs of crime – for example, by providing education and legal income opportunities to destitute people who are at risk of becoming offenders. The deterrence argument leaves open the empirical question whether money spent on monitoring and sanctioning (taxing illegal behavior) deters crime more efficiently than money spent for subsidizing legal behavior. Nonetheless, Becker and many other advocates of “negative” deterrence seem to focus from the outset on harsh penalization.

While Becker (1968) praised Beccaria as the first one to have used economic calculus in the study of crime, their ideas differ markedly: first, Becker favored capital punishment. Second, he did not elaborate on the effects of the celerity of capture and punishment. Third, he did not believe that *low-size-high-probability sanctioning* (**Beccarian deterrence**) deters crime more effectively than *high-size-low-probability sanctioning*, as proposed by himself (**Beckerian deterrence**). Based on expected utility theory, he argued that Beccarian deterrence would only work better if people were risk preferring (which is not plausible). In contrast, increasing the size of punishment and decreasing its probability, while maintaining its expectation value, will reduce the utility of illegal behavior and thus deter crime more effectively if people are risk averse (which is plausible). Becker claimed that his sanctioning regime would be superior even if people were risk neutral because it would deter crime as effectively as Beccarian deterrence but allow regulators to economize on enforcement costs. Kolm (1973: 266) pointedly highlighted the weak spot of the Beckerian conclusion as “*hang offenders with zero probability.*”

The legal doctrine regarding punishment:

Despite its label, *economics of crime* is commonly seen as encompassing the study of criminal and noncriminal offenses. This loose terminological usage would not be acceptable for legal scholars.

Criminal lawyers will note that the penal code differs substantially from other codes of laws and that its provisions must be limited to reflect society’s most fundamental moral sentiments of right and wrong. Inversely, it is to provide a stigma capable of causing social costs to criminals and shaping the norms of people. That is, less forceful legal institutions such as administrative and tort law should be used to outlaw less serious misconducts. Otherwise, the reciprocal links between the criminal law and society may erode which, in turn, may cause perverse behavioral effects and the degradation of the criminal law system.

Legal doctrine (cf., Radbruch 2011) must reject Becker’s normative conclusions for three reasons. *First*, Becker’s internalization approach transfers the liability rationale of tort law to criminal law. Like administrative law, tort law does not provide a strong stigma. Hence, many ordinary (noncriminal) people find it acceptable to occasionally break civil or administrative law provisions (minor torts or violations of building law, traffic law, etc.). Becker suggested that even crime be accepted if it facilitates an efficient allocation of resources. The criminal law, however, must stigmatize crime – be it “efficient” or not – more than other transgressions because crime not only reallocates resources but also violates the inalienable individual rights of a person and the universal rights of society as a whole. *Second*, legal scholars will not endorse the all-dominant role of the expectation value of the sanction, and they will reject the suggestion to adjust the size of a sanction contingent on its probability of being imposed. The justice system must not only produce deterrence but also be proportionate and fair to the individual person (proportionality principle). The rule of law requires a transparent uniformity of the law aimed at meeting equal crimes with equal punishment. This precludes subjecting individuals

committing minor transgressions such as parking offenses to extreme punishment (“hanging”) on the sole ground that detection probability is low. *Third*, practically minded legal scholars will add that it is not possible to differentiate sanctions contingent on specific enforcement contexts. Imagine a city council that reduces the number of police officers for budgetary reasons. In Becker’s view, this would require adjusting the sanction catalog in this city and punishing offenders, who are caught despite slack enforcement, more severely. How should the lawmaker learn about each city’s specific circumstances? What about law adjustment costs? Moreover, how should presumptive offenders learn about the sanctions in place?

It seems that the normative recommendations of conventional *economics of crime* are often not feasible from a legal doctrine point of view. This is because conventional *economics of crime* pays notoriously little attention to legal requirements that limit the set of deterrence strategies available to regulators. Following its recommendations would more often than not violate fundamental legal principles and compromise the rule of law.

Neoclassical approaches to deterrence are not naïve. They do not deny that individual behaviors are frequently incompatible with the axioms and predictions of rational choice. They contend, however, that deviations from the standard model are minor or at least symmetrical (Korobkin and Ulen 2000). In their view, it is therefore adequate to model people as rational and self-interested utility maximizers even if there is not a single individual in the world who is a fully rational egoist. For illustration sake, let us look at the “supply” of a criminal act such as theft. If people’s evaluations were randomly distributed around a mean defined by a risk averse rational egoist, the utility obtained from theft (and thus its “supply”) could be predicted to decrease

if regulators, while maintaining the expectation value of the sanction, compensated low risks of punishment with high sanction levels. However, this will not hold if the regulatees’ *perception* of the detection risk is *asymmetric* because they underrate or even neglect small probabilities. In this case, Beckerian (high-size-low-probability) sanctioning will prevent less crime than Beccarian (low-size-high-probability) sanctioning. If people’s judgments are affected by such **systematic biases** (either generally or in certain social groups), understanding these biases will enable regulators to better predict and eventually influence people’s behavior.

In Beccaria and Bentham’s view, highly certain and swift punishment is needed to make people fully *perceive* the association of crime with punishment. These early pioneers seem to have anticipated cognitive features that behavioral economists today would classify as forms of bounded rationality, namely, “**nonlinear weighting of probabilities**” and “**hyperbolic discounting**.” Beccaria and Bentham apparently realized that people might underrate or neglect small probabilities and be biased towards the present. When both effects combine, people will attribute a high value to the immediate benefits of crime and a very low or no value to its high but uncertain future costs. This seems a plausible explanation of many rule breaking instances including illicit drug use with its mainly self-inflicted future punishment of bad health or even premature death. Nonetheless, Becker disregarded bounded-rational judgments and was convinced that one can dispense with all other theories including those of “psychological inadequacies.” He believed *his* theory of crime and emphasis on harsh punishment to be an improvement on not only Beccaria but all crime scholars who do not exclusively rely on the neoclassical paradigm. Due to frustrating experiences with harsh punishment, many scholars today think that Beccaria was right to advocate mild but certain and swift punishment. Nevertheless, Becker and his followers, backed up by the electorate’s liking for harsh punishment, seem to have had an influence that partly reverted crime policies, especially in the USA, back to premodern penalization

regimes with capital punishment, long prison sentences, and mass incarceration. Even though heavily criticized on methodical grounds, a time-series analysis by Ehrlich (1975), claiming that capital punishment substantially reduced capital crimes in the USA, fueled this development. Using more adequate econometric approaches, more recent studies did not find that capital punishment deters capital crime (e.g., Zimmerman 2004; Kovandzic et al. 2009).

Behavioral Economics of Crime

There is considerable evidence from experimental and observational studies that, for various reasons, people’s behaviors deviate substantially *and* systematically from rational choice predictions (Thaler 2016). This is why regulatory strategies exclusively based on the neoclassical paradigm, which is still mainstream in law and economics, are a socially inefficient way to prevent illicit behaviors in many contexts. An educated guess would be that they could work for tax offenses and securities fraud but less so for street and property crimes or drug offenses.

A **behavioral-economics-of-crime** analysis that provides a reconstructing understanding of perpetrators’ judgments is needed to close the gap between rational choice predictions and actual behavior. Instead of relying on rational choice and objective facts, **reconstructing understanding** implies trying to understand people’s options of choice and calculi according to their subjective perceptions and evaluations. As Rubinstein pointed out (1991: 910), “these

[perceptions] need not necessarily represent the physical rules of the world.” As people are heterogeneous in both their goals and judgments, making reliable predictions and identifying adequate enforcements strategies is a challenging task. It is also a promising task because many laws address specific groups whose members share behavioral regularities. Such regularities can be identified and considered when specifying contextual enforcement strategies. Adequate strategies will substantially differ, for example, between fields such as securities legislation, traffic law, or drug law. A promising regulatory potential termed “**nudge**” by Thaler and Sunstein (2008) arises from the fact that people’s behaviors often depend on how contexts are described or “framed” (Tversky and Kahneman 1981). Finally, people’s goals and judgments change and can be shaped (to a certain degree) over time.

Table 1 itemizes a selection of deviations from rational choice that seem especially relevant for the study of illegal behaviors. The large number of “anomalies” – as they would be labeled from the neoclassical point of view – forces us to limit this entry to a brief and focused description of those deviations that seem to be most relevant for understanding compliance decisions. Further descriptions regarding behavioral economics applications with respect to noncompliance can be found in Dhami (2016), Thaler (2016), or Korobkin and Ulen (2000), for example.

Multiple Goals, Social Norms, and Bounded Self-interest

People’s utility does not exclusively hinge on material outcomes including leisure and

Crime: Economics of, Different Paradigms, Table 1 Deviations from rational choice relevant for the study of crime

	Loss aversion	Mental accounting	Limited attention

conveniences. In contrast, people have complex **multidimensional goal systems** that are influenced by the apparently innate human urge to repay both good and bad experiences in kind (**reciprocity**). Besides the self-interested pursuit of material benefits, people particularly strive for two types of intangible outcomes: (1) conformity with external social expectations and (2) consistency with internalized values and norms. These intangible goals can limit people's self-interest (**bounded self-interest**). Different labels have been attached to these two behavioral drivers. Psychologists often speak of an extrinsic as opposed to an intrinsic motivation to comply. Coming from an applied management research background, Nielsen and Parker (2012) use the terms "social preferences" as opposed to "normative preferences." Adopting an institutional economics perspective on rule-governed social life in general, Ostrom (2005) speaks of external as opposed to internal "*delta* parameters" to indicate that social norms have to be considered as behavioral drivers in *addition* to material incentives.

Criminology with its primary focus on the law and law enforcement provides still another terminology and talks of "protective factors" and "risk factors" (Hirschauer and Scheerer 2014). **Protective factors** are bonds to social norms that discourage illicit choices by causing non-material costs for rule-breaking and nonmaterial benefits for rule abidance. Protective factors can be seen as mechanisms that impose "intangible taxes" on illegal acts and provides "intangible subsidies" for legal acts. These taxes and subsidies arise from external social control (social disapproval/ostracism vs. social approval) as well as from internalized values (self-disrespect/guilt vs. self-esteem). Protective factors can be related to the concept of **resilience**. Instead of seeing people as being either law-abiding or criminal, this implies understanding people as being more or less resilient to moral hazards in that they have a positive but limited willingness-to-pay for rule abidance in exchange for social approval and a feeling of integrity.

In contrast, **risk factors** arise in deviant subcultures in which social norms are not in line with those of the law-approving "conventional"

society. Examples are youth gangs, organized crime communities, or groups hostile to state authority due to extreme religious or ideological beliefs. Like protective factors, risk factors can arise from external and internal sources. They act as "intangible taxes" for legal behaviors (disrespect by deviant peers and conflict with the deviant internal self) and as "intangible subsidies" for illegal behaviors (respect by deviant peers and affirmation of the deviant internal self). Altruistic rule-breaking and **reactance** (Miron and Brehm 2006), for example, are internal risk factors resulting from a deviant self. Even though frequently neglected, risk factors and protective factors are often decisive for compliance decisions. Group-specific social pressures and rewards to break the law, in conjunction with weak conventional norms against illegal behavior or outright deviant selves, for example, are likely to be more relevant causes of juvenile delinquency, such as illegal road races or vandalism, than illicit profits. The interplay of protective factors and risk factors is also crucial for understanding how individual employees behave within deviant corporate cultures (multiple-selves problem).

Crime prevention is an intentional manipulation of factors that determine people's behavior with regard to the law. Three ideal-type strategies are distinguished (Picciotto 2002): **incapacitation** (e.g., through license withdrawal or jailing) is aimed at reducing would-be perpetrators' opportunities to commit offenses. **Deterrence** (e.g., through monitoring and sanctioning) is to reduce the economic temptations (incentives) for rule breaking. **Accommodation** (e.g., through persuasion and advice) is to bolster people's propensity to comply by strengthening the social norms that back up the rules (protective factors). For example, informing defaulting taxpayers that the majority of people in the same town have already paid their tax debts was found to have a positive effect on tax compliance (The Behavioural Insights Team 2011).

Identifying adequate prevention strategies requires a normative analysis based on conditional forecasting. In this forecasting exercise, the behavioral effects of economic incentives and norm-based "taxes" and "subsidies" cannot

be considered in isolation. Reducing the economic attractiveness of rule breaking through tight controls and harsh sanctions may reinforce social norms in some instances but weaken them in others. The label “**crowding in**” describes interventions that simultaneously provide the “right” incentives and strengthen desirable social norms. Evidence from fields as far apart as industrial safety and tax legislation indicates that successful strategies manage to crowd in (Braithwaite 2009). They avoid the dysfunctional effects of oppressive control and harsh sanctions (e.g., reactance) as well as the negative effects of overly lenient approaches (blurring of standards). In contrast, “**crowding out**” describes interventions that involuntarily weaken desirable social norms in the attempt to reduce the economic temptations for rule breaking (Frey 1997). An illustrative example comes from a field experiment in daycare centers (Gneezy and Rustichini 2000). After a small fine was introduced for collecting children late, the frequency of late pickups increased. The interpretation by Sandel (2012) is that under the old regime parents tried hard to be in time because they were ashamed to cause inconvenience for the staff. After the introduction of the fine, which doubtlessly increased the economic costs of coming late, parents felt no shame anymore but came to see late pickups simply as an extra service for which they paid a “fee.”

The intended primary effect of criminal sanctioning is often not economic deterrence. Instead, one hopes that the social stigma provided by the penal law, such as banning the beating of children, will reinforce desirable social norms. Including offenses into the penal code may backfire if the values of the lawmaker and of those subjected to the law do not correspond. Criminalizing activities that many people do not consider “real” wrongs may weaken the criminal law’s general capacity of cultivating social norms. What is more, it might provoke **perverse effects** beyond those caused by the weakening of crime-inhibiting social norms. For example, criminal sanctions on the use of soft drugs, while increasing its cost, might actively encourage substance abuse if users develop individual reactance or even group norms that favor defying what they

consider illegitimate and oppressive government intervention.

With a focus on corporate governance and recidivism, Braithwaite (2002) emphasized that a transparent progression of regulatory responses – accommodation first, deterrence second, incapacitation third – is needed to fully exploit the steering potential of regulatory enforcement. Using the terms “**enforcement pyramid**” and “**responsive regulation**,” he claimed that regulators should meet noncompliance always with a clear disapproval and the request to remedy the wrong. They should use increasingly severe deterrent measures (warning letters, tightening controls, increasing fines) if offenders continue to break the rules. As a last resort, recidivists should be subjected to increasing levels of incapacitation (license suspension, license revocation, jailing). Braithwaite’s key message is that regulators should aim to reintegrate offenders into rule-abiding society by using *transparent* and *graduated* response measures contingent on the degree of bad/good conduct. While regulators should always start softly, the concept of responsive regulation, which is inherently aimed at crowding in, is not leniency. On the contrary, it assumes that the harsher the available ultimate sanctions, the more likely regulators will achieve compliance through persuasion. The recommendation to regulators would therefore be to “speak softly, while carrying very big sticks” (Ayres and Braithwaite 1992: 40).

Bounded Rational Judgments

Besides social norms and bounded self-interest, bounded-rational choice needs to be considered when trying to understand and steer people’s behavior. The term “**bounded rationality**” was coined by Simon (1957) to describe that individuals have limited access to decision-relevant information and that they have limited abilities to process that information. Consequently, choices are often biased and may depend on the presentation of the decision problem (framings) even if the framings have no effect whatsoever on outcomes. To reduce complexity and cope with their bounded-rationality, people often use simplifying decision rules or “heuristics”

(Gigerenzer and Todd 1999). **Cognitive biases, heuristics, and bounded self-control** can lead to choices that are contrary to rational choice expectations according to which fully informed people judiciously weigh the costs and benefits associated with their choices.

Nonlinear weighting of probabilities: Expected utility theory assumes linearity in the weighting of probabilities. In contrast, Kahneman and Tversky (1979) claimed, on the one hand, that people frequently underweight high probabilities and overweight low probabilities. On the other, they noted that people's perception is reversed near the end points in that very high probabilities are perceived as certain, whereas very low probabilities are underrated or even ignored. In the context of crime, the latter misconception is sometimes fueled by "optimism bias" (Weinstein and Klein 1996), which describes a person's belief to be less prone to risks and negative events than others. An important source of such misconceptions are premature generalizations from personal experiences that are easily mentally available and thus salient ("availability bias"). Illicit behaviors associated with low sanctioning probabilities, such as traffic offenses or free-riding public transport without a ticket, are illustrative examples. They may become business as usual for offenders who repeatedly experience no controls. The ostensible remedy of making the risk of being caught more salient by disclosing the number of caught offenders may produce perverse effects, however. For example, while such a piece of information clearly points out to free-riders that the probability of being caught is *not* zero, nondelinquent individuals might adjust a previously overrated detection probability downwards which, in turn, might produce some new free-riders. What is more, obtaining the knowledge that free-riding is a common phenomenon might erode the social norm that backs up the formal obligation to purchase a ticket. In this context, Popitz (1968) spoke of the "preventive effect of ignorance."

Overconfidence bias: Offenders are not average representatives of the population. At least a certain subset of wrongdoers may overestimate their capabilities and believe that they are more apt and clever to commit crimes and avoid

punishment than others. What is more, they may also have the disposition to interpret even quite unambiguous information in ways that fall into place with their preconceived notions ("self-serving bias"). Overconfidence and self-serving bias can explain "silly" crimes for which no explanation in terms of the criminal's self-interest can be found. Deterrence strategies that target presumptive offenders who exhibit overconfidence and/or self-serving bias need to strengthen the salience of controls and sanctions. This may require increasing controls and sanctions beyond the level that would be needed to deter unbiased offenders.

Loss aversion: People often do not think in terms of final states but rather in terms of changes that they perceive as gains or losses with respect to a reference point (Markowitz 1952). Kahneman and Tversky (1979) claimed that people experience losses about twice as strongly as gains. The perception of a change as either a gain or a loss depends on contexts/framings and can affect compliance. Imagine two tax regimes. In regime 1, a taxpayer has to pay 1,000 in income tax per month. In regime 2, the total tax debt of 12,000 is payable after the end of the tax year. In both regimes, tax dodgers run a 25% risk of being detected and fined to pay a penalty of 48,000 in addition to the 12,000 in due taxes. Rational choice theory would predict that taxes are paid lawfully in both regimes because the *expected* reduction in income amounts to 15,000 ($= 0.25 \cdot 60,000$) in the case of tax evasion, but only to 12,000 in the case of lawful tax payment. In addition, tax evasion would increase income *risk*. Things are different if the taxable person exhibits loss aversion. In regime 1, such a taxpayer is likely to perceive the income level *after* regular monthly tax payments as reference point and experience the taxes as nonrealized income gains (opportunity costs). In regime 2, the taxable person is likely to get used to the income level *before* paying taxes and correspondingly adjust the reference point upwards. From the increased reference point, paying the tax debt of 12,000 will be perceived as a certain loss (out-of-pocket costs) that, despite being identical, is experienced as a heavier burden than the taxes in regime 1.

Depending on the strength of this effect, the taxable person in regime 2 will evade taxes and exchange the certain loss for the uncertain chance to escape tax payments. From a rational choice point of view, this implies behaving like a risk seeker. Loss aversion can be related to status quo bias and, more particularly, the endowment effect. The latter describes the fact that people find it generally hard to part with goods and wealth they already enjoy and (believe to) legitimately own.

Habits: Depending on the familiarity with and the relevance of choices, individuals either rely on habitual behaviors or consciously resort to problem-solving procedures (Katona 1953). Each day, people need to make so many choices that they must be made fast. This is why most choices are not the result of analytical procedures. Instead, people cannot help but make most choices habitually and spontaneously. This has been labeled “thinking fast” by Kahneman (2011). Having a habit means making the same choices as in the past when dealing with recurring or similar decision problems. Habits are arguably the most important heuristic without which we would not be able to survive. Habitual behaviors can be important for understanding some types of illegal behaviors. Depending on the individual’s life course, offenses such as speeding or even evading taxes may have become subconscious habits irrespective of whether they provide noteworthy benefits for the offender or not. Habits in conjunction with self-serving bias may pose serious obstacles to effective deterrence, which is inherently based on informing people about controls and sanctions. This is because people are prone to dissolve cognitive dissonances by aligning their interpretation of information to their deep-set habitual behaviors (self-manipulation of beliefs) instead of aligning their behaviors to the information.

Adhering to defaults: Default options seem to exercise a stronger influence on people’s behavior than what we would expect when considering the usual small effort needed to opt against the default. An illustrative example is people’s acceptance to become organ donors (Gigerenzer 2010). The willingness to donate organs is considerably lower in countries that use “no organ donation” as default compared to countries that apply the

nudge device of making “organ donation” the default option. A plausible explanation is that individuals orient themselves to what they perceive as the socially desired standard. People’s preference for the as-is state (the default) can also be understood as a habit or a special form of the “status quo bias.”

Mental accounting: People occasionally classify their choices into categories or “accounts” (health account, environment account, etc.) within which they offset their choices against each other (Thaler 1999). Imagine dog owners who mentally enter “paying dog tax” and “cleaning up when walking the dog” to the same account. After the introduction of a dog tax, they might feel that they can offset their cleaning up against their paying the dog tax. The important message is that introducing new regulations can have negative side effects that are easy to overlook. The effect produced by mental accounting looks like crowding out at first view. The difference is that mental accounting describes how the levels of *different* activities, which people see as belonging to the same “account,” affect each other. Crowding out, in contrast, looks at *one* activity and describes that incentives might involuntarily weaken favorable social norms.

Hyperbolic discounting: The conception of rational choice includes the concept of time preferences that assumes that people discount future outcomes by using their individual rate of time preference. They presumably do so, however, by using constant discount rates per period. In contrast, behavioral economists note that people often exhibit a “*bias* towards the present” in that they prefer the present more than what would be expected from a rational choice perspective. To be more precise, instead of discounting consistently over time, they apply very high discount rates per period for outcomes in the near future but falling discount rates the further in the future the outcomes arise. This has been termed “hyperbolic discounting” (Phelps and Pollak 1968). It constitutes myopia in that people who are prone to hyperbolic discounting consume more in the present than what they had previously planned. Thaler (1991) illustrated the phenomenon by noting that most individuals would inconsistently prefer one apple today to two apples tomorrow but

two apples in 51 days to one apple in 50 days. Crimes associated with drug addiction provide illustrative examples for hyperbolic discounting. If punishment does not follow swiftly, it will not work as a deterrent because addicts attribute a very high value to the fulfillment of their immediate cravings but a very low value to future costs. In the case of strong addictions, juvenile delinquency, and extreme social deprivation, hyperbolic discounting may be so strong that deterrence based on punishment, which is inevitably separated from the offense by a certain time lag, will not work at all. The stronger the presumptive offender's hyperbolic discounting, the swifter the punishment must follow to work as a deterrent.

Emotions: Many emotions arise from people's social interactions and the apparent human need to reciprocate good as well as bad experiences. Emotional behavior can be related to myopia and hyperbolic discounting in that people succumb to immediate behavioral urges without being able to judiciously consider the future consequences and the legality of their actions. Examples are crimes of passion – directed against individuals by whom the offender believes to have been wronged – such as violent acts of rage or revenge committed at the height of an emotional crisis. The analytical potential of economics of crime, which is inherently based on the assumption of *purposive* action, is limited in the case of spontaneous acts committed in the heat of the moment. But not all emotional crimes are undeliberated acts caused by failing self-control. Instead, some crimes of passion are planned well in advance. The same holds for hate crimes that are directed against people for no other reason than their belonging to certain groups (homosexuals, Jews, people of color, refugees, etc.). People in democratic countries with a high level of economic prosperity are not immune to hate crimes. For example, refugees are often met with anxieties and fears that are amplified by social media echo chambers and exploited by populist politicians. In a hostile public atmosphere, members of deviant political subcultures may feel invited to even physically attack refugees and volunteers without prior reason.

Limited attention: Some noncompliance instances are due to the fact that people make

mistakes because they are forgetful and because they can only pay attention to a limited number of issues at a time. If someone focuses strongly on one matter, other issues may receive too little or no attention despite being relevant (Simons and Chabris 1999). Not paying taxes in time or not complying with the complex legal codes of practice in food production, for example, is often not the result of purposive action but the result of negligence caused by the individual's limited attentiveness. This does not rule out an economic approach. Negligence can often be economically deterred because the rule addressees can and will use additional resources and manpower to avoid negligent mistakes if they are more tightly controlled and sanctioned or made liable for damages.

²Department of Economics, Universidad del Rosario, Bogota, Colombia

Definition

Economics of crime aims at studying, theoretically and empirically, which are the determinants of criminal behavior and how it is affected by incentives and punishment. In 1968, Becker presents a paper that radically changes the way of thinking about criminal behavior. Since the beginning of 1980s, Becker's paper opens the door to a new field of empirical research whose main purpose is to verify and study the economic variables that determine criminal choices and behaviors of agents.

Introduction

In 1968 Gary Becker published "Crime and Punishment: An Economic Approach," a paper that radically changed the economic approach to analyzing criminal (as well as all types of illegal) behavior. Criminal choice conduct is not determined by mental illness or bad attitudes. Rather, it is an individual's *choice*, based on a maximization problem in which agents compare the costs and benefits of misbehavior. The costs are given by the probability of being arrested, the likely punishment, and the gain that is forgone by engaging in a crime instead of in legitimate market opportunities. The benefit is the expected return from committing the crime. Thus, in the Beckerian framework criminal decision-making responds to an economic analysis of agents.

The development of this "rational" approach to criminal behavior, in economics and other social

sciences, was favored by "redistributive" and "utilitarian" theories of crime, proposed respectively by Cesare Beccaria (Beccaria 1819) and Jeremy Bentham (1789). In "On Crimes and Punishments," Beccaria argued that crime represents a violation of the social contract, and thus punishment is justified only to defend the social contract and to ensure that everyone will abide by it, deterred from engaging in criminal activities. In turn, in "An Introduction to the Principles of Morals and Legislation," Bentham – largely influenced by Beccaria, first introduced the idea that crime is the consequence of a cost-benefit analysis. He writes: "The profit of the crime is the force which urges man to delinquency: the pain of the punishment is the force employed to restrain him from it. If the first of these forces be the greater, the crime will be committed; if the second, the crime will not be committed" (p. 33). The imprint of the two philosophers on Becker is conspicuous.

The first economics studies of crime came, however, over 200 years after the seminal writings of Beccaria and Bentham. In the 1960s, before Becker's "Crime and Punishment," Belton Fleisher explored the relationship between unemployment and youth crime (Fleisher 1963), and the role of income on the decision to engage in criminal activities (Fleisher 1966). Fleisher was the first economist to analyze empirically the relationship between crime and economic and social variables. However, it was Becker (1968)'s general theoretical framework of crime as an individual's rational choice, what constituted the starting point for analyzing criminal behavior – as well as crime control policies – from an economics perspective.

In his 1993 Economics Nobel Prize acceptance lecture, Becker underlies that while "[i]n the 1950s and '60s, intellectual discussions of crime were dominated by the opinion that criminal behavior was caused by mental illness and social oppressions, and that criminals were helpless victims," the economics approach "[i]mplic(s) that some individuals become criminals because of the financial and other rewards from crime compared to legal work, taking account of the

likelihood of apprehension and conviction, and the severity of punishment." (p. 5).

We now briefly review Becker's basic model of how individuals choose between legitimate and illegitimate activities, basing their decision on a cost-benefit analysis. In Becker's own words "[t]he approach (...) follows the economists' usual analysis of choice and assumes that a person commits an offence if the expected utility to him exceeds the utility he could get by using his time and other resources at other activities. Some persons become 'criminals', therefore, not because their basic motivation differs from that of other persons, but because their benefits and costs differ" (p. 176).

Specifically, Becker defines a supply of offences (O), which relates "the number of offences by any person to his probability of conviction (p), his punishment if convicted (f) and a portmanteau variable (u), such as the income available to him in legal and other illegal activities":

$$O_j = O_j(p_j, f_j, u_j)$$

An agent's choice is made under uncertainty, then the *expected* utility from committing a crime is defined as:

$$EU_j = p_j U_j(Y_j - f_j) + (1 - p_j) U_j(Y_j)$$

where Y_j the income ("monetary plus psychic") of committing a crime, and f_j "the monetary equivalent of the punishment." The expected utility is also determined by the probability of getting away with the crime: $1 - p_j$. The supply of crime is thus decreasing p and f .

To Becker, optimal policies to combat illegal behavior are those that minimize the "social loss" that crime entails. He defines the social loss function from offences as:

$$L = D(O) + C(p, O) + bfpO$$

where D is damage from crime, C the cost of apprehension and conviction, and $bfpO$ is the total

social loss from punishments. Here, the social policy variables are represented by p (the probability of arrest) and f (the punishment). The parameter b aggregates individual offender costs of punishment into a social cost. Solving the model with respect to the policy instruments p and f , while taking into account the equilibrium supply of offences, Becker obtains important implications on agents' propensity toward risk. Crime reduction can occur through reducing the benefits of crime, or else from raising the probability of being caught or the costs of punishment conditional upon being caught. Also "a rise in the income available in legal activities or an increase in law-abidingness due, say, to 'education' would reduce the incentive to enter illegal activities and thus reduce the number of offences" (p. 177).

In 1973, Isaac Ehrlich extended Becker's model, allowing individuals to allocate time between legal and illegal market activities, as well as in nonmarket activities. While Becker's agents are either criminals or not at all (given their cost-benefit calculation), Ehrlich models more sophisticated individuals, in the sense that they can spend time in different activities, both legal and illegal.

In spite of the similarities between Becker's basic model and Ehrlich pioneer (Ehrlich 1973), and subsequent (Ehrlich 1975, 1996) refinements, an important contrast is Ehrlich (1981)'s distinction between the "deterrence" effect of criminal sanction (considered by Becker the sole role of policing and incarceration) and the "incapacitation" effect that locking-up criminals has on crime reductions, by impeding felons to rejoin the crime industry once they are released. In Ehrlich's own words, "deterrence essentially aims at modifying the 'price of crime' for all offenders, potential and actual. (...) [I]ncapacitation, in contrast seek(s) to remove a subset of convicted offenders from the market for offences either by relocating them in legitimate labor markets, or by excluding them from the social scene for prescribed periods of time" (p. 311).

Theoretical refinements of this sort can only improve the design of policies for crime

prevention and crime reduction. After all, the primary objective of Becker himself was to "...use economic analysis to develop optimal public and private policies to combat illegal behavior" (p. 207). Today, the "economics of crime" literature pays constant tribute to the father of the field, with a growing and vibrant set of applications of the basic cost-benefit, rational approach to individual's illegal behavior.

Crime: Expressive Crime and the Law

Martin A. Leroch

Politics and Economy, Johannes Gutenberg
Universität Mainz, Mainz, Germany

Abstract

Expressive crime contrasts with instrumental crime in that delinquents aim to "make a statement", and not to "make a living". This difference in motivation has important consequences for the deterrent effect of policies. Whereas policies aiming at expected material costs of perpetrators have often proven successful in deterring instrumental crime, they may fail to deter delinquents with expressive motivations. In some cases, perpetrators may even feel defied to increase their activity.

Definition

Expressive crime is a form of illegal behavior which is motivated by the desire to communicate personal attitudes to others. It contrasts with instrumental crime, which is motivated by the desire to gain material objects.

Crime (Expressive) and the Law

Crime may be distinguished along several dimensions. One such dimension focuses on the motivation underlying illicit actions. Accordingly, while instrumental crime is motivated by the desire to "make a living," expressive crime is motivated by the will to "make a statement." Examples of instrumental crime include robbery, stealing, and fraud, while suicide terrorism, illegal political protests, or the spraying of graffiti constitute examples of expressive crime. Some incidents of crime share both components. For instance, severely beating up a debtor who owes money to a criminal organization may on the one hand be regarded a signal or statement to others

that they better repay their debt. On the other hand, this message per se is instrumental in acquiring more riches.

Distinguishing crime according to its motivation is important for the design of policies to deter criminals, one of the major foci of economists, as has been argued, for instance, by Cameron (1988), Kirchgässner (2011), or Robinson and Darley (2004). In theory, deterrence can be achieved either by increasing the probability of detection or by reducing the utility levels of detected delinquents. For the case of instrumental crime, this theory appears valid, at least in parts. While there is evidence that policies aiming at increasing detection probabilities may be successful (e.g., in Klick and Tabarrok 2005), most studies call into question the deterrent effect of increases in available punishment. In cases of expressive crime, however, an increase in detection probabilities or punishment may even lead to perverse effects of increases in both number and intensity of illicit behaviors. The reason for these effects is that punishment may promote crime by affecting “the values of certain other variables ... which in turn have a direct effect on deviant behaviour” (Opp 1989, p. 421). Crucial for this crime-promoting effect are indirect effects of punishment, which change the (social) incentive structures for perpetrators. Opp finds support for the defiance of perpetrators in examples of legal and illegal political protest, two prominent forms of expressive behavior.

What makes expressive crime so susceptible for these indirect effects of punishment is its signaling property. By making their illegal statements, perpetrators want to send signals to others, for instance, their peers or their opponents. For instance, perpetrators may wish to signal their opponents that they are dissatisfied with the current organization of society or with certain decisions of the current government. Likewise, they signal their active peers that they do not “stand alone” with their attitude. Because the costs associated with transmitting the signal affect its “quality” positively, delinquents may choose to send more (and/or stronger) signals when harsher means of deterrence are employed. Deliberately facing armed forces on the street, for instance,

may transmit the signal that I am willing to incur physical pain in order to show others that I disagree with certain policies of the current government. The more likely physical pain is, or the more pain I am to expect, the better I can signal my disagreement. The willingness to incur this pain may also increase my standing among peers – assuming that all peers share opposition toward the government and agree that illegal protest is an adequate form of expressing this opposition.

If standard means of deterrence prove counter-effective, the question of how to counter expressive crime evolves. Addressing the signal value of illicit behaviors or the signal as such appears the most promising strategies. The fight against graffiti in New York City’s underground provides a vivid example for such a strategy. After being considered a serious problem in the 1970s, the city managed to almost entirely free its subways from graffiti by 1989. Apparently, the crucial change in strategy was to prohibit sprayed trains from running. Any train leaving the depot was cleaned from graffiti entirely before being brought to service. Sprayers thus knew that spraying was no effective way of transmitting their signals any longer (sprayers typically want to signal disagreement with capitalist ways of organizing society, express artistic desires, or gain attention from others. See Leroch (2014) for a more detailed analysis of graffiti spraying), and they stopped spraying on subways. Cities around the globe copied this strategy successfully in the fight against graffiti.

Crime: Organized Crime and the Law

Matthew J. Baker

Hunter College and the Graduate Center, CUNY,
New York, NY, USA

Abstract

This entry reviews the literature on the economics of organized crime. While the economics of organized crime is a small subfield of economics, it can offer insights in unexpected areas of economics. The field began some 40 years ago with the study of organized crime and its participation in illicit activities such as prostitution and gambling. Over time, the economic analysis of organized crime has expanded to address broader questions of governance in the absence of formal institutions.

Introduction and Background

The economic literature on organized crime constitutes a rather small portion of the field of law and economics. That having been said, it offers some interesting and unexpected insights into questions of interest to economists. Since its beginnings 40 or so years ago, economic research on organized crime has expanded from a somewhat narrow focus on illicit markets into a broad study of patterns in organizational formation and collective decision-making. The result is that economists' study of organized crime has contributed to the understanding of things of fundamental importance, such as the economics of governance and the formation and organization of property rights.

The phenomenon of organized crime first attracted the interest of economists in the late

1960s and early 1970s. The interest can be attributed to enthusiasm for Becker's (1968) development of an economic theory of criminal behavior and decision-making and also to policy interests deriving from the 1967 report of the President's Racketeer Influenced and Corrupt Organizations (RICO) task force and ensuing adoption of the Organized Crime Control Act of 1970. Initial work focused mainly on description of industries often associated with organized crime, such as loan-sharking, gambling, prostitution, and narcotics, to name a few (see Kaplan and Kessler (1976) for several illuminating examples). Schelling (1967, 1971) provided the first theoretical apparatus for thinking about organized crime. From his initial theoretical steps, the definition and study of organized crime has evolved toward the view that the criminal organization is in fact a form of nascent government, which often arises to perform the usual government functions of enforcement and policing in sectors of the economy where the government is either unable or unwilling to do so.

Defining and Theorizing About Organized Crime

Activity-Based Analysis

Defining organized crime is a difficult task, and, as noted by Fiorentini and Peltzman (1995b, Chapter one) in their review of the literature, research on organized crime has to some degree been driven for a search for an adequate definition of the subject (incidentally, the publication of Fiorentini and Peltzman (1995a) was something of a watershed moment in the economics of organized crime. It is required reading for anyone interested in the economics of organized crime, as is Fiorentini (2000). In fact, this entry has been written with the twin objective of covering necessary ground yet complementing these earlier works in mind). Accordingly, their characterization serves as a useful starting point for characterizing the economic literature on organized crime (defining organized crime is also a difficult multidisciplinary puzzle. See Finckenauer (2005)). As alluded to in the "Introduction" and as Fiorentini

and Peltzman (1995b, Chapter One) emphasize, the first attempts at the definition of organized crime were activity based. A criminal organization was deemed to be one that operates either in full or in part in illegal or illicit markets such as gambling, loan-sharking, and prostitution. Analysis focused on description of the growth and evolution of organized crime in particular industries, operational details, and estimation of the overall size of the industry. One might include in this category even earlier descriptions of the growth and expansion of organized crime, such as analyses of the rise of the American Mafia during Prohibition or analyses of the growth and organization of the Sicilian Mafia (see, e.g., Cressey (1969), who provides a thorough description of the history and nature of organized crime in the United States). One illustrative example of a lucid industry description is given by Kaplan and Matteis (1976) who discuss the day-to-day workings of a loan-sharking operation. Much of this early literature emphasizes that the criminal organization tends to provide goods and services which are illegal, but for which there is nonetheless consumer demand, such as narcotics or prostitution (one might maintain that the development and growth of the Mafia has less to do with serving illegal markets and more to do with filling a vacuum of power. In this way, early literature on the Mafia might have more in common with the theories based upon the development of property rights under anarchic circumstances, which are discussed in section “[Governance and Crime](#)”). Kaplan and Matteis (1976), to continue the example, note that loan sharks are specialists in offering credit to an unserved segment of the market: high-risk, short-term borrowers. Of course, description of industry is essential to its study, and this tradition is, thankfully, still very much alive in the economic literature (see, e.g., Bouchard and Wilkins (2010)).

Extortion and Crime

Schelling (1967, 1971) represents the initial break with the activity-based approach to the study of organized crime and also is the first to present a cohesive theoretical structure for thinking about the economics of criminal organizations. His

point of departure is that a criminal organization is in essence an extortative body. As such, its primary goal is to maintain monopoly control of illicit activities (and maybe even legitimate ones) for the purposes of rent extraction – protection money. There is no real reason, according to Schelling, that prostitution or gambling or other illicit activities have to be monopolized, but they are obvious targets for extortion because they need some degree of visibility to operate and benefit from regular customer bases, but could not operate as effectively without some shield from the law. Moreover, industries like prostitution and gambling are easily monitored for purposes of rent extraction, as things like income and provider ability are easily monitored.

Schelling’s view is attractive in that it has some ability to explain other aspects of organized crime, such as why organized criminal organizations so often engage in turf wars. Buchanan (1973) parlayed Schelling’s position into a supplementary theoretical argument offering some good news for society: since illicit activities are by and large those that society deems unacceptable (social “bads”), monopolization of these activities by criminal organizations actually produces a social benefit, as these goods will tend to be underprovided. Backhaus (1979), however, takes exception with this position, noting that, among other things, there are likely to be scale economies in organizing illicit activities. Thus, a monopolist might provide more illicit goods and services to the market.

The first big challenge to the theory evinced by Schelling came from Reuter (1983), who analyzed a broad array of empirical and historical evidence on organized crime and found that Schelling’s approach did not always match the facts. In particular, Reuter (1983) emphasized that much organized criminal activity seems to be more competitive than monopolistic (or perhaps at least monopolistically competitive), in that many small, independent entities often provide illicit goods or services in the same market area. Some years later, technical aspects of this observation were taken up by Fiorentini (1995), who developed a former mathematical model of oligopolistic competition in illegal markets. He finds that it

is difficult to draw exact conclusions about how resources invested in violence, corruption, or provision of the goods depend upon the degree of competition and that the answer depends in a critical way on what sort of response criminal organizations expect from the government. This result in fact foreshadows results emanating from recent research on organized crime, governance structures, and imperfect enforcement of property rights. A model in a similar vein is presented by Mansour et al. (2006). They ask how it could be the case that, while deterrence expenditures increased throughout the 1980s and 1990s in the United States, criminal output (e.g., output of drugs) increased and prices fell. The essential idea derives from allowing market structure to respond to the pressures of deterrence; if deterrence creates more competition, output may well expand.

An alternative tradition that also departs from the theory proposed by Schelling, owing originally to Anderson (1979) (see also Anderson (1995)), is a transaction cost approach to studying organized crime. Anderson, in her description of the development and organization of the Sicilian Mafia, argues that transaction costs are important drivers of organized criminal activity. Dick (1995) provides a more expansive transaction cost analysis, which emphasizes what even casual observation suggests are universally important practical problems presented by illicit exchange, such as commitment, credibility, and maintenance of contracting arrangements and long-term relationships. Polo (1995) presents a formal theoretical model capturing credibility and commitment in a long-term setting that bears resemblance to models of contracting and commitment in settings in which agents cannot rely on formal institutions, as in Clay (1995) and Greif (1993). Turvani (1997) also attacks the problem of organized crime from a transaction cost economics perspective.

Governance and Crime

In the early 1990s, an alternative way of thinking about the organized criminal organization as a kind of nascent state emerged. This theoretical approach grew out of the literature on endogenous

development and enforcement of property rights in conditions of anarchy, usually associated with the initial efforts of Skaperdas (1992), Hirshleifer (1988), and Grossman and Kim (1995). One essential idea of this work is that security is, at the end of the day, a good like any other, and while the government typically provides it, when it does not, some other actor will invest in the provision of security. Milhaupt and West (2000) provide some data-based empirical support for the idea that illicit activity expands due to inefficiencies in state provision of property rights. Skaperdas and Syropoulos (1995) present a model in which rival gangs allocate resources to both production and security of what is produced. Grossman (1995) models a situation in which a criminal organization arises as a “rival kleptocrat” to the government; that is, the Mafia comes about as a rivalrous organization defending property rights and extracting resources from producers, just as the government imposes taxes. One interesting aspect of Grossman’s argument is that the populace might actually benefit from the competition in services provided by the criminal organization. It both expands the amount of protective services available and also limits rent extraction by the licit government.

This view of the criminal organization was subsequently further developed and expanded upon. Skaperdas (2001) provides an expansive view of historical evidence through this lens. At the same time, more sophisticated views of markets and interactions have been applied to the study of organized crime as well as the basic idea that the criminal organization operates in conjunction with the government and is to some degree fueled by the inadequacy of bureaucrats and provision of basic government services. For example, Kugler et al. (2005) present a model in which criminal organizations compete in a “global” market in providing products, but intercede only locally in bribery of bureaucrats. They find increased deterrence could, in some circumstances, lead to higher crime.

Indeed, this branch of literature has evolved toward the position that the governance and security problems which criminal organizations arise to deal with are not all that different from the

problems of social organization faced by human populations throughout history. Skaperdas and Konrad (2012) provide a model in which self-governance is possible and indeed a best-case scenario for the populace. It is, however, less stable and susceptible to more predatory styles of government, and unfortunately, the more competition in the market for protection, the worse things become. Similarly, Baker and Bulte (2010) focus on the Viking epoch beginning around 800 AD and describe how Viking raids – which might be thought of as organized criminal activity – became more and more sophisticated, even as measures to prevent raiding grew more sophisticated.

Internal Structure, Participation, and Deterrence Policy

The basic facts underlying the internal structure of criminal organizations are ingrained in popular myth, yet deeper details and analysis have been a bit harder to come by (of course, much of the work cited in this entry contain institutional detail. See, e.g., Skaperdas (2001) and Anderson (1979)). There is a large empirical and theoretical literature on the decision to participate in crime dating from Becker's (1968) paper, but the decision to participate specifically in organized crime has received considerably less attention.

The notable exception is Levitt and Venkatesh (2000), who analyze in detail the finances and internal structure of a Chicago drug-selling gang. The gang analyzed by Levitt and Venkatesh has a hierarchical structure with a highly skewed wage scale. Those at the bottom of the hierarchy are paid minimal fixed wages for what is dangerous and risky work. Those at the top of the hierarchy do considerably better, motivating Levitt and Venkatesh to suggest promotion and wages are to some degree governed by a rank-order tournament. Still, they find it is difficult to reconcile gang participation with optimizing behavior if one only considers pecuniary rewards from participation. A further finding of Levitt and Venkatesh is that those in the lower echelons of the gang often simultaneously participate in

legitimate markets; this suggests that members of the lower rungs might be peeled off by targeted policy interventions.

Garoupa (2000, 2007) explicitly focuses on the internal, vertical structure of the criminal organization using principal-agent theory. Garoupa (2000) follows a more or less classic model of enforcement and deterrence, but allows that offenders must pay a fee to a monopolist agent (i.e., the Mafia) to commit a crime. A key result is that less severe enforcement policy may be optimal than it would be in the absence of a Mafia. Garoupa (2007) works in the same framework, but focuses on a wider assortment of potential punishments and different dimensions of the organization, such as how many agents the organization will seek to hire and how mistake-prone the organization will be in light of its size and, ultimately, the sort of punishments it faces. One result of interest is that severe punishment may reduce organizational scope, but increase organizational effectiveness.

Conclusions

While the economic literature on organized crime remains small, within this literature, a considerable measure of historical detail and methodological diversity has been used in its study. Perhaps the most striking thing about the literature on organized crime is that the very different methodologies employed in its study all recommend a degree of care in thinking about its prevention and deterrence. The recurring theme is that heavier investment in policing and punishing organized criminal activity may have unexpected and unpleasant consequences. The sophistication, competence, and extent of the organization may respond in ways contrary to intuition. In the current domestic and international atmosphere, illicit market activity in the form of international drug and human trafficking remains a major concern, as do the terrorist and other non-state organizations which arise whenever and wherever in the world there is a vacuum of power. In light of this state of affairs, the key insights offered by the literature on organized crime seem to be well worth emphasizing.

Criminal Constitutions

Nicholas A. Snow

Department of Economics, Indiana University,
Bloomington, IN, USA

Definition

Criminal constitutions exist in a number of different criminal enterprises, from the Golden Age of Pirates to modern prison and street gangs. The purpose of these constitutions is to better facilitate cooperation among organizational members in order to help better achieve profit maximization.

Criminal Constitutions

It is easy to imagine criminal organizations being composed of lawless, all out for their own chaotic individuals but this is far from the truth. From an economic perspective, especially since Gary Becker's famous 1968 publication, *Crime and Punishment: An Economic Approach*, the starting point for analyzing criminal behavior is to assume that criminals are rational agents. From this perspective, it is not surprising to find that many black markets and other criminal organizations are extremely orderly and rational. This is, of course, not to say that they are desirable or morally good but if we are to truly understand criminal organization it is important to analyze them in truth and not in fiction.

Many criminal organizations are not only rational and orderly but also formally created as such. For example in his 1991 book, *Islands in the Streets*, Jankowski found that 22 out of 37 street gangs had written criminal constitutions. And street gangs are only one of numerous examples of criminal organizations having deliberately written and constructed constitutions that attempt to align the self-interests of its members to that of the group interest, such as eighteenth century pirates, prison gangs, the Mafia, etc. Additionally, other black markets without formal constitutions

will often still contain informal and implicit criminal codes that exist to do the same thing, such as the market for smuggled liquor in Detroit in the United States in the 1920s under alcohol prohibition as illustrated by historian Larry Engelmann's 1979 book, *Intemperance, the Lost War Against Liquor*.

The reason for the emergence of such criminal constitutions is simple. Black market firms are still firms and as such act in order to maximize profits. Economists Leeson and Skarbek, in a 2010 article, *Criminal Constitutions*, highlight three main reasons for the emergence of criminal constitutions. The first is that constitutions help to create common knowledge about what the organization expects from its members and the different members can expect from each other. This helps to align expectations among participants within the organization and in the broader market setting. Common knowledge is often created by having explicit rules, whether written or not, of how to behave within the organization and without. This has the advantage of members knowing exactly what they are getting themselves into by joining the organization in terms of duties, rewards, obligations to other members, etc. Rules may also consist of entrance requirements for potential members. By knowing the rules when you come into the organization, current members can have more confidence in the new members.

Second, criminal constitutions help to solve the principle agent problem within criminal organizations. It is often the case that members of the various criminal organizations are not necessarily the residual claimants of the organization, thus making them particularly vulnerable to divergent interests. The rules within the constitutions, and their enforcement, can help to make sure that divergence of interests does not take place. For criminal organizations this may be extremely important. For example, as Leeson explains in his 2009 book, *The Invisible Hook*, a pirate's profitable enterprise consists of plundering on the high seas. This is often hazardous work. In the act of successfully plundering a merchant vessel, pirates might be required to

engage in a dangerous battle. Individual crew members may recognize the high costs of participating in battle to themselves. Thus, a collective action problem emerges because the individual pirate's incentive is to stay out of the fight but the more pirates that think like this, the less likely the ship is going to be taken. Profit maximization requires pirates to take as many ships as possible. Therefore, pirates created rules and rewards to encourage all individuals to engage in battle when necessary, such as providing, what essential boiled down to, workman's compensation for injury and special rewards for particular courage.

Finally, criminal constitutions create information about member misconduct and help formulate rules and enforcement that prohibit such behavior. This final function is self-enforcing because conflict within any organization will necessarily cut into the profits of the illicit firm. If members of the gang are constantly fighting, then they are not engaged in productive efforts, which earn the organization profits. As Skarbek illustrates, in his 2014 book, *The Social Order of the Underworld*, prison gangs even utilize rules of conflict for preventing intra-gang conflicts. Violence is costly for business, so the gangs have an incentive to enforce rules among their own members to avoid unnecessary conflict even with competing gangs.

The main distinction facing illicit organizations from legal organizations is the lack of access to formal governance institutions necessary for markets to properly function and flourish. Given the illegal nature of their activities, criminal organizations are unable to turn to legal and social institutions, which help to enforce private property rights, contracts, and facilitate collective action agreements. It is for this reason that most black markets consist of many, very small, and ephemeral enterprises. Thus, contrary to conventional wisdom, large monopolies are often a rare occurrence within black markets. While the use of violence is often unlikely to have an effect on this structure, it is, however, likely to have an effect on profit opportunities for the different organizations within the market. Constitutional arrangements

are then able to help facilitate cooperation within and between organizations.

Ultimately, as profit maximizing organizations, criminal organizations use constitutions in order to help facilitate cooperation among its various members to help ensure higher profits for the organization. This certainly seems strange considering these organizations are made up of individuals who are openly flaunting the governments laws but when understanding that just like a legitimate firm, criminal organizations wish to maximize their profits, it becomes clear why such rules would emerge. Markets need rules to function and because of their illicit nature the government is not an option for providing such rules, thus the organizations will create these rules in order to facilitate the gains from trade.

Criminal Sanctions and Deterrence

J. J. Prescott

Law School, University of Michigan, Ann Arbor, MI, USA

Abstract

This entry defines criminal sanctions by distinguishing them from civil sanctions, and briefly surveys the major categories of criminal sanctions, both ancient and new. The entry then outlines the primary social justifications for using such sanctions—focusing on deterrence as a distinct purpose of punishment—and describes a basic model of criminal offending to highlight the conditions under which the threat of criminal sanctions can influence offender behavior in predictable ways. Next explored are the implications for deterrence of the different types of criminal sanctions. A brief discussion of the suggestive conclusions emerging from related empirical evidence follows.

Definition

Criminal sanctions are punishments (e.g., imprisonment, fines, infliction of pain, or death) imposed by governments on individuals or corporate entities for the violation of criminal laws or regulations. Deterrence, one of the principal theories used to justify the use of criminal punishment, occurs when the possibility that an individual will be subjected to a criminal sanction were he to commit a crime causes the individual to forgo or engage in less of the behavior in question. Deterrence is the primary justification for punishment in the field of law and economics.

Introduction

To address socially harmful (or potentially harmful) behavior, governments enact laws (or groups

of people develop practices) to sanction or punish individuals who choose to engage in it. If the problematic behavior rises to a particular level of harmfulness or has particular features (e.g., physical violence), the behavior may be classified as criminal, and upon conviction, a violator will, by definition, receive some sort of criminal sanction. The distinction between a criminal sanction and a civil sanction is largely one of degree and possibly just semantics, although many scholars have attempted to carefully delineate the two spheres. There is a credible argument that a crime is simply a harmful act that the government decides to label a crime (perhaps because it is seriously harmful but perhaps not), and a criminal sanction is simply a sanction the government applies to someone who has performed such an act.

This entry will begin by briefly exploring what may make a sanction “criminal” in nature and then by summarizing the key categories of criminal sanctions. Some types of criminal penalties are largely historical relics; others are innovative and rely on modern technology. Nevertheless, sanctions of more recent vintage, such as constant, real-time GPS monitoring, share many features with more traditional varieties. This entry will primarily focus, however, on deterrence—specifically, its definition and how the imposition of criminal sanctions can achieve this fundamental purpose of punishment. Basic features of the economic model of crime will be described (see Becker 1968), and a variety of topics relevant to criminal deterrence will be covered, including the model’s theoretical predictions for offender behavior, the implications for deterrence of employing different categories of modern criminal sanctions (including their unintended consequences and the potential for sanction complementarity when they are used simultaneously), and the consensus conclusions of the empirical literature.

Criminal Versus Civil Sanctions

What makes a sanction a “criminal” sanction? The cleanest answer to this question is the tautological response that “a criminal sanction is a sanction that seeks to punish someone for having committed a

crime,” thus begging the question: “What makes a particular act a crime?” One important attribute of a crime is that the act or its consequences be socially harmful. But the category of “harmful” behaviors is ultimately socially constructed through some aggregation of individual preferences and beliefs and is therefore determined simply by whether a government decides that the act in question is indeed harmful enough to be worthy of public censure. Some harmful acts are not subject to government sanctions for practical or philosophical reasons. When a government decides to discipline someone who has engaged in a harmful act, it selects between or some combination of “civil” measures (traditionally, fines) and criminal sanctions.

It is impossible to identify conditions that, without exception, distinguish a crime from another form of civil wrong, like a tort. But there are tendencies, or characteristics, that make a certain harmful act more likely to be labeled a crime. One important criterion is the mental state of the wrongdoer. Crimes are usually (but by no means always) done knowingly or intentionally or at least involve a blameworthy awareness of risk; otherwise innocent acts that accidentally result in harm, however, are rarely considered crimes, and sometimes even intentional acts that cause harm are merely intentional torts (Miceli 2009, p. 269).

Other suggested criteria relate to the difficulties that harmed individuals (or their friends or family) might face (as a group) in privately enforcing particular prohibitions. For example, when particular categories of wrongdoers might be difficult to identify (e.g., thieves), using specialists may make sense, and the average victim is certainly no specialist (Polinsky and Shavell 2007, p. 406). Likewise, if the nature of the harm is widespread, enforcement may be a public good. No single private individual may have the incentive to pursue the wrongdoer. As Miceli (2009, p. 270) points out, extreme examples of this category are “victimless” crimes (e.g., possessing child pornography or drugs) in which the harms are often thought to be the knock-on, indirect consequences of the activity.

Some argue that the civil/criminal wrong divide maps to the liability/property rule

distinction in the law (Miceli 2009, p. 273). Under this rubric (see Calabresi and Melamed 1972), civil wrongs are those for which there is, ultimately, a price, usually set by the court *ex post* in the form of damages awarded in a civil trial. By contrast, the enactment of a criminal prohibition can be viewed as the granting of an inalienable right to potential victims by the government. There is no dollar figure that an offender can pay to rectify the violation of this right. Rather, the offender must be punished, and the punishment has no necessary relationship to (and is usually much greater than) any damages sustained by the victim.

Even better, however, would be the prevention of the harm *ex ante*, since it is in some sense irreversible. This is consistent with criminal law often being publicly enforced by specialists (Shavell 2004, p. 575), as *ex ante* prevention by private individuals seems much less likely to succeed relative to winning an *ex post* lawsuit.

Types of Criminal Sanctions

Typical criminal sanctions in modern countries include fines, incarceration, and supervision (including probation and parole). The death penalty (or capital punishment) is a historically important criminal sanction, but it is employed rarely in practice in Western countries these days and is treated elsewhere in this collection.

Fines. When a fine is imposed, an offender is legally ordered to pay to the state or perhaps to a third party the levied amount, perhaps in lump sum or perhaps in installments under a payment plan. Fines are limited in their effectiveness as a punishment by the assets or potential assets of the offender (and by extension, the offender’s ability to work or otherwise access resources) and by the capacity of the government to collect the fine, through garnishment of wages, for example.

Incarceration. Imprisonment or incarceration more generally is perhaps the best-known and most common form of criminal sanction in the modern world, at least with respect to serious crimes. The “quantity” of imprisonment varies by the conditions of the imprisonment (e.g., amount

of space, cleanliness, quantity or quality of food, available or required activities, access to other prisoners, access to loved ones, and so on) and by the time the offender is sentenced to remain imprisoned.

Intermediate Sanctions. Intermediate or alternative sanctions are typically viewed as less serious than incarceration: the offender is released from (parole) or never sentenced to (probation) incarceration but remains free only by compliance with specified conditions, which can be affirmative obligations or negative restrictions.

Traditional forms of intermediate sanctions are increasingly common, at least in some jurisdictions—e.g., home detention, mandated community service, and mandatory drug treatment. Other forms of punishments are considerably less common. For example, rare at least in most Western countries is the imposition of the death penalty, the killing of an individual by the government as punishment for the commission of a crime. Corporal punishment, the deliberate infliction of pain as punishment for a criminal offense (e.g., caning or whipping), is still practiced, although today only in a small minority of countries and with significant limitations.

Governments, including many in the USA, also employ shaming as a criminal sanction—i.e., subjecting an offender to public humiliation as a form of punishment. Historically, these punishments were often accompanied by an element of physical discomfort or of physical or verbal abuse (e.g., stocks or pillory). Modern shaming punishments retain the humiliation element and perhaps allow verbal abuse by the public, but do not typically impose conditions that might result in extraordinary physical discomfort or pain. Finally, banishment, as a form of punishment, is the mirror image of incarceration. Rather than an offender being required to be in a particular place, he is required to leave the community altogether in order to isolate that individual from friends and loved ones and to eliminate any future threat to the community.

Many of the most innovative criminal sanctions in recent years have emerged in response to public concern over sex offenses, especially in the USA. In the 1990s, sex offenders were

believed to be highly likely to return to sex crime upon release from incarceration, and many such offenses are serious crimes; as a result, governments developed new criminal sanctions that manage to combine elements of incapacitation, shaming, and banishment.

Sex offender registration, for example, is an extremely weak form of incapacitation. When required to register, offenders must provide identifying information (e.g., name, date of birth, address, criminal history) to law enforcement to facilitate the latter's monitoring and, if necessary, apprehension of them. Consequently, committing a new crime becomes more difficult for an offender who in some sense weighs the costs and benefits of his options. Mandatory real-time GPS monitoring of an offender's location is a more technologically advanced version of registration. If monitoring equipment is visible to others when it is worn, shaming also occurs, much like the proverbial wearing of a scarlet letter.

Community notification is a stronger form of incapacitation, coupled with a different form of shaming. When an offender is made subject to notification, the government releases identifying registry information to the public, which increases the overall level of monitoring, prompts potential victims to take precautions (in theory creating a bubble around the offender), and subjects the offender to humiliation, to great difficulty in finding employment and housing, and potentially to more active forms of abuse at the hands of members of the public. Yet while GPS monitoring equipment may result in humiliation in every one-on-one interaction with another person if the equipment is visible, an individual living under notification, even when the notification is an active form (e.g., neighbors of an offender receive a card in the mail containing the offender's registration information), is not physically marked as a sex offender and so may have anonymous interactions without humiliation.

Sex offender residency restrictions are a targeted form of banishment. Offenders living under residency restrictions are not necessarily forbidden from a particular place under all conditions. However, offenders cannot lawfully live within a certain distance of places where potential victims are particularly likely to frequent. Other types of

restrictions—travel restrictions, employment restrictions, and so on—function in the same way, by banishing offenders either from places where or from roles in which they are assumed to pose the most threat.

Under many criminal justice systems, offenders are sentenced to combinations or bundles of different kinds of criminal sanctions. For example, sentences that include both fines and incarceration are common, as are sentences that begin with incarceration but are followed by parole or some other form of supervision. These combination sanctions may be attempts to pursue multiple purposes of punishment simultaneously (e.g., a fine can punish, but it cannot incapacitate, at least not to the extent that a prison cell can) or they may be an attempt to punish more efficiently. For example, as we will see below, fines can be more efficient as a form of punishment because they are a transfer, but most offenders are liquidity constrained and so fines have only limited utility in most circumstances. Finally, there may be economies of scope in using a cluster of criminal sanctions as a consequence of behavioral tendencies, including, e.g., hyperbolic discounting. Increasing a sentence from 5 to 6 years may be less effective at altering behavior than adding a comparable fine or other restrictions to a 5-year sentence.

Finally, while not formally sanctions, arrest and criminal process by themselves will result in many financial, psychic, and opportunity costs (see Eide 2000, pp. 351–352 for a discussion of these—e.g., lost employment and legal fees), and these costs have the potential to affect an individual's decision to engage in crime (e.g., Bierschbach and Stein 2005).

Purposes of Criminal Sanctions

The application of criminal sanctions to an offender is usually justified in one of two ways. Retributive theories are premised on the idea that, by committing the crime, the offender has become morally blameworthy and is deserving of punishment. A criminal sanction does justice (for society, for the offender, for the victim) by punishing the offender, with the degree of

punishment having a direct relationship to the seriousness of the offender's moral culpability (which in turn has some relationship to the seriousness of the harm), at least according to some retributive views. Utilitarian theories, by contrast, are forward looking, focused on future consequences: a criminal sanction is appropriate if the benefits that follow from imposing the sanction outweigh the costs and suffering of its imposition. The punishment that generates the most net benefit is morally preferable. Mixed theories of punishment draw from both sets of ideas, usually with the hope of accounting for our intuitions about whether and how much punishment is appropriate. For instance, certain limited forms of retributivism assume the consequences of criminal sanctions matter at the margin but that moral desert establishes constraints on the levels of punishment that are minimally required and maximally permitted.

Economists are primarily interested in utilitarian or consequentialist theories of punishment, and in setting punishments, they seek to maximize net social welfare by reducing the total harm that results from crime—including the administrative costs and consequences to offenders of imposing criminal sanctions, in addition to the harms suffered by victims of crime and society. In practice, criminal sanctions can reduce future harm in one of three ways, although these categories are not always precisely demarcated: rehabilitation, incapacitation, and most important from the perspective of economists, deterrence.

Rehabilitation involves using criminal sanctions to change the preferences of offenders or to improve an offender's range of legal choices, thereby making the commission of crime less attractive. Incapacitation entails increasing the costs to the offender of making illicit choices or simply limiting the number of illicit choices available (Freeman 1999, pp. 3540–3541). In the latter case, incapacitation can succeed even in the face of an entirely irrational offender. For a discussion of the economics of these purposes of punishment as well as brief notes on the economics of retribution, see Shavell (2004, pp. 531–539).

Deterrence assumes at least some offenders are at least somewhat rational, which means that

they must be capable of responding to incentives and to their environments generally, a proposition that seems obviously true (Shavell 2004, p. 504). When deterrence can work, it is particularly attractive because sanctions need only be employed when an individual breaks the law. In the limit, if deterrence is perfect and there are no law enforcement mistakes, then society can achieve the first best (at least if any benefits to an offender of committing a crime are not included in the calculus): no harm comes to victims and no harm comes to potential offenders. What is more, the nature of the criminal sanction is unimportant, so long as deterrence is complete. Outside of this extreme, however, the relative advantages of different criminal sanctions matter a great deal in determining the socially optimal punishment regime.

Economic Model of Crime and Deterrence

There are at least a few different ways to conceive of developing an economic model of crime. The most straightforward starts with a set of crimes fixed by assumption (e.g., by taking the set of criminal prohibitions enacted by a government as given and simply assuming it includes the harmful acts society ought to criminalize). Analysis then begins with the question: "What steps should the government take to minimize the aggregate net harm of these acts?" To simplify matters, the discussion below proceeds largely using this framing of the problem.

As suggested above, however, a more general approach to the economic model of crime begins first by endogenously identifying specific harmful acts (either because they are harmful in themselves or because they risk harm) that are socially undesirable (Shavell 2004, p. 471). According to the standard economic account, a socially undesirable act is one in which the expected social benefits that result from the act (which may or may not include gains that accrue to the offender) are outweighed by its associated harms. Theoretically, categorizing acts in this way requires comparing the social costs and benefits of the act under all potential enforcement regimes

(including no enforcement), making the problem anything but trivial. For certain harmful acts, even the most efficient method of enforcement will prove too costly (Shavell 2004, p. 486); in these cases, minimizing harm is best accomplished through decriminalization, leaving it either to private parties to enforce through civil enforcement mechanisms or to social norms (Polinsky and Shavell 2007, pp. 446–447).

Starting with the categories of acts it considers sufficiently undesirable to criminalize (or with all acts if the set will be endogenously determined), society seeks to minimize the net social harm (or maximize the net benefit) from these, potentially using criminal sanctions in combination with other policies.

The economic model of crime focuses on the individual offender's decision to commit one of these acts, asking whether, given the offender's preferences and environment, his individual benefits of proceeding outweigh his individual costs of doing so (Becker 1968). Most economic models of crime assume that at least some share of potential offenders are capable of responding in predictable ways to incentives created by criminal sanctions (Eide 2000, pp. 352–355). If individuals are incapable of rational behavior in this sense, then enforcement of any kind must be premised either on rehabilitation or incapacitation or both. By assumption, criminal prohibitions are enforced through the probabilistic application of criminal sanctions. The optimization problem is how best to select and structure the application of these sanctions, given their costs and the likely response of relevant actors. Again, this approach may mean allowing certain harmful acts to go unpunished.

Modeling Criminal Behavior

Suppose an individual considers committing a criminal act instead of engaging in some legal (perhaps income-generating) activity. Assume the relative benefits to that individual for carrying out the act *absent* a public enforcement regime (net of the forgone benefits from the competing legitimate activity) amount to b_o . Note that there may also be some social benefit to this act, either b_o (i.e., if society "counts" the gains to the offender and there are no other benefits) or some other lesser or

greater amount, which we may call b_s . By assumption, b_s will not affect the decision of the offender to engage in criminal activity, but b_s may affect whether society ought to label the act a crime as well as how best to enforce any prohibition. If b_o is positive, then by definition the individual will engage in the activity, absent some threat of a criminal sanction.

Now assume a public enforcement regime is in place, and if the offender is caught engaging in the now-prohibited activity, he will be apprehended and criminally sanctioned (e.g., fined or imprisoned for some length of time). This sanction is costly, both to the individual (s_o) and possibly also to society (s_s) (again, s_s may be larger or smaller than s_o).

Public enforcement of criminal prohibitions is infused with uncertainty. Not all criminal activity is detected; if it is detected, not all of it results in an arrest; if the activity results in an arrest, not every arrest results in a conviction that leads to a sanction (Nagin 2013, pp. 207–213). Furthermore, there is the possibility of plea bargaining—i.e., “settlements dilute deterrence,” as noted by Polinsky and Shavell (2007, p. 436). Even the formal criminal sanctions announced after conviction are sometimes overturned on appeal or adjusted down the road (e.g., early release). Often, there is also a considerable time lag between the commission of a crime and the application of any sanction to the offender.

At the same time, in some contexts, arrests and criminal process function in effect as additional punishment (conditional only on arrest) because dealing with the police and with criminal allegations is also costly, regardless of whether the offender is ultimately convicted of the crime. At an even more basic level, anxiety over possible detection increases the effective severity of any potential punishment. Criminal sanctions also result in other lost opportunities and collateral consequences not captured by the formal sanction itself (e.g., loss of employment).

Finally, uncertainty also cuts the other way: individuals innocent of any crime may be wrongfully convicted of a crime (Polinsky and Shavell 2007, pp. 427–429), which means even deciding to forgo committing a harmful act does not

completely insulate someone from criminal sanctions, although we assume that the probability of a criminal sanction is much higher if the person engages in the prohibited activity.

Let p represent the net increase in the probability that an individual is punished if he chooses to commit the criminal act in question, taking into account all of the considerations outlined above. In effect, p implicitly adjusts for the fact that a criminal sanction ultimately imposed (i.e., experienced) is very different from the one laid out in the law. With certainty, p will not only be less than one (unless detection is extremely high, as it may be for some crimes) but will also be greater than zero, at least in any society in which law enforcement does not arbitrarily mete out punishment. Importantly, p is likely to be specific to an individual; some individuals are better able to avoid detection and conviction, and others are presumably more likely to be wrongfully prosecuted or subjected to more onerous criminal process.

The phrase “deterrence is a perceptual phenomenon” (e.g., Nagin 2013, p. 215) refers to the ideas that (1) the offender must perceive the threat of being criminally sanctioned in order to reasonably expect the offender’s behavior to change and that (2) an offender will only be deterred to the extent of the *perceived* level of enforcement or severity of the criminal sanction. Legal systems typically assume that individuals are aware of the law as it appears on the books, and potential offenders typically have some sense of the potential consequences they face for engaging in criminal behavior, but any such knowledge is imperfect (Shavell 2004, p. 481). Allow $f(p \times s)$ to represent a function that captures how potential offenders perceive threatened criminal sanctions and public enforcement more generally. Again, this perception is specific to an individual (Eide 2000, p. 352), as some individuals will be more experienced, better educated, and so on.

These assumptions and this notation allow us to characterize the decision of the potential offender as willing to commit an offense (rather than engage in some other lawful activity) if the net expected utility (relative to alternatives) is positive: $u_o(f_o(p_o \times s_o), b_o) > 0$. Put in the simplest of terms, the potential offender weighs the

net benefits of harmful conduct (absent any threat of enforcement) and compares this to the perceived net individual costs of becoming subject to criminal enforcement. Note that this margin is, by assumption, net of competing legal opportunities that are otherwise available to the individual. Potential offenders who expect to receive relatively large net benefits from the illicit activity, those who underestimate public enforcement efforts, and those who do not expect to suffer as much as others from any sanction, for example, are more likely, all else equal, to choose to offend.

Assuming some level of offender rationality and access to information, the model tells us that society can influence an offender's calculation (and therefore behavior) by changing (1) the level or type of criminal sanction (s_o), (2) how it will be enforced and how likely it is to be enforced (p_o), (3) how the sanction and enforcement are perceived ($f(\cdot)$), and (4) the net benefit (relative to legal pursuits) to the offender of the activity (b_o). Deterrence research traditionally focuses on the first two variables (on the theory that they are more policy relevant), taking into account the potential offender's preferences and other relevant attributes (particularly, risk aversion and wealth or income levels). Reducing the returns to undetected crime also matters in this model, however, and society can always modify potential offender behavior by altering an individual's preferences, although the analysis is agnostic on how a society might accomplish this.

Importantly, a complete theory of optimal public enforcement incorporates this range of strategies and the expected response of offenders to each of them, but also much more that is beyond the scope of this entry's discussion. Identifying how to maximize a social welfare function requires not simply accounting for the effects on offender behavior of criminal sanctions and the degree of enforcement (deterrence). Also vital are the social costs of these activities (Polinsky and Shavell 2007; Miceli 2009), including consequences for victims. Here, the focus is not the optimal enforcement bundle, but deterrence alone—specifically, what models and empirical work can tell us about changing offender behavior by altering

criminal sanctions and, to a lesser extent, enforcement levels.

Theoretical Predictions

In a simple deterrence framework, the predictions of how changes in criminal sanctions or enforcement levels affect behavior follow fairly straightforwardly from traditional ideas about consumer choice (or labor supply) and decision making under uncertainty (see, e.g., Freeman 1999). As Eide (2000, p. 345) puts it, deterrence theory is “nothing but a special case of the general theory of rational behavior under uncertainty. Assuming that individual preferences are constant, the model can be used to predict how changes in the probability and severity of sanctions. . . may affect the amount of crime.” For the sake of brevity, the discussion below concentrates principally on the potential effects of increasing or decreasing criminal sanctions or the degree of enforcement effort and on the consequences of using different types of criminal sanctions.

To organize the discussion, observe the following: First, as theoretical work makes clear, a potential offender's attitude toward risk (whether risk averse, risk neutral, or risk preferring) has significant implications for criminal behavior in virtually every remotely realistic model of deterrence (e.g., Eide 2000, p. 350). Second, the consequences of different risk attitudes differ depending on the policy lever in question, whether it is the level of enforcement activity, the severity of the criminal sanction, or the type of criminal sanction.

Furthermore, it is important to recognize that theoretical work and empirical evidence on deterrence and offender behavior are most useful in the interior of the policy choice set, not at the extremes. Shavell (2004) has written that “optimal law enforcement is characterized by under deterrence—and perhaps by substantial under deterrence—due to the costliness of enforcement effort and limits on sanctions” (p. 488), implying, if it is not already obvious, that a nontrivial portion of potential offenders will not be deterred in any reasonably practicable regime. At the same time, no one doubts criminal sanctions deter in some basic sense if viewed from the perspective

of lawlessness, whether zero sanctions or no enforcement. As Robinson and Darley have stressed in a number of articles (e.g., 2003, 2004, among others), the relevant policy question is whether criminal sanctions deter effectively *at the margin* or whether long prison sentences deter more effectively *relative to* more moderate but still significant sentences.

Begin by stepping back from the model laid out above and consider perhaps the simplest choice environment available: the decision to allocate a fixed amount of money between legal and illegal activities (see Schmidt and Witt 1984, pp. 151–154). The legal investment provides a certain return; the illegal investment offers a higher return, but the possibility of apprehension (p) and a fine (s) makes it uncertain. The relative returns of these investments vary continuously across investors in such a way as to create two corner solution groups; some proportion makes only legal investments, while others make only illegal investments. Now, consider an increase in p . In all states of the world, the illegal investment offers a weakly lower return, and so under minimal conditions, some proportion of investors near the cutoff move from making illegal investments into making legal investments, regardless of risk preference. Similarly, an increase in the fine (s) also lowers the return on average and weakly in all states, and it does so in a way that generates significantly more risk; so assuming risk aversion or risk neutrality, deterrence also occurs (with fewer illegal investors). These outcomes align roughly with Becker's (1968) conclusions, which suggest that increasing fines rather than enhancing the degree of enforcement will prove more effective at deterring criminal behavior, assuming potential offenders are risk averse.

A more complicated scenario emerges from a somewhat more realistic framework that allows for leisure time as an element of the utility function, even with simplifying assumptions. Imagine a potential offender considering an act enforced by threat of a monetary fine. Assume the crime in question is fraud and the benefit is monetary and that the offender could otherwise spend the time lawfully employed, earning wages with certainty, or enjoying leisure. For ease, assume that u , f ,

and b and any nonlabor income are fixed and that the initial values of s and p would result in the offender choosing to commit at least some fraud but also realistically engaging in a minimum of some leisure.

What are the effects of increasing either the size of the fine (s) or the degree of enforcement (p)? A portfolio or labor supply analysis provides the answer: because an increase in either s or p would effectively reduce the "return to crime," the prediction is ambiguous. The substitution effect alone will typically point in the direction of less crime (or fewer people engaging in crime), but the income effect may point in the opposite direction, depending on offender attitudes toward risk. More precisely, when the question is which of these two effects dominates, the "tipping point" is determined by the curvature of the utility function (i.e., by the level of risk aversion).

In many deterrence models (Eide 2000, pp. 348–350), the results do wind up supporting casual deterrence intuitions—i.e., that raising p or s results in less time devoted to crime (Eide 2000, p. 347)—but a great deal always turns on risk attitudes. And, as the models become more realistic, other technical conditions, such as the effect on the illegal gain if the offender is apprehended, become important. Schmidt and Witte (1984, p. 160), for instance, report that even the *source* of a change in p (e.g., an increase in the arrest rate versus an increase in the conviction rate) can result in a stronger or weaker prediction. In their most complicated (read: realistic) deterrence model, Schmidt and Witte (1984, p. 164) acknowledge that unambiguous predictions are not possible without four strong assumptions regarding (1) attitudes toward risk, (2) net returns to crime and the net gains to crime if the individual is convicted, (3) how the marginal utility derived from one activity changes with the time allocated to another, and (4) the way in which the marginal utility of an activity changes with a change in income. They conclude their excellent review (on which Eide (2000) and this entry both draw heavily) by noting:

Economic models that allow either the level of sanctions or the time allocation to enter the utility function directly are more appealing intuitively. They allow individuals to have different attitudes

toward sanctions, work, and illegal activity, and they answer the question of how leisure is determined. However, this increased realism is not without its price. These models do not allow us to determine unambiguously how changes in criminal justice practices or opportunities to conduct legal activities will affect participation in illegal activities. The ultimate effect of stiffened penalties [(*s*)], increased probabilities of apprehension [(*p*)], or improved legal opportunities becomes an empirical question (Schmidt and Witt 1984, p. 183).

Still, as between increasing criminal sanctions (*s*) or increasing the degree of enforcement (*p*) as a means of reducing criminal activity, deterrence models support the relative robustness of increasing *p*, given the possibility that offenders may be risk loving. As Eide (2000, p. 347) generalizes, “[b]oth the probability and the severity of punishment are found to deter crime for a risk averse person. For risk lovers, the effect of severity of punishment is uncertain.” However, if *p* is disaggregated into the probability of arrest, the probability of conviction conditional on arrest, and so on, different conclusions are possible with respect to the “conditional” levers (Schmidt and Witt 1984, p. 160). It is worth reiterating that other technical assumptions also matter to whether these models can generate useful predictions, such as whether all costs and benefits can be monetized and the precise nature of the enforcement probabilities (Eide 2000, p. 350).

Finally, in most of these models of offending behavior, the level of risk aversion will affect how *p* and *s* can be combined to achieve a certain level of deterrence. When risk aversion levels are high, for example, increasing the severity of sanctions will be a comparatively easier strategy for increasing the offender’s costs of criminal activity (Shavell 2004, p. 480).

Types of Criminal Sanction: Implications for Deterrence

A rich theoretical literature exists on the relative merits of using monetary fines and nonmonetary sanctions, like incarceration. Many of the key results, however, turn on the social cost of imposing the sanction in question. For instance, all else equal, fines are superior to imprisonment because, theoretically, a fine is less expensive to impose

and is effectively just a transfer from the offender to society (i.e., “utility” is destroyed by incarceration, not transferred to someone else). Of course, comprehensive summaries of these results like Shavell (2004) and Polinsky and Shavell (2007) also acknowledge that sanction type is relevant to offender behavior in the first instance and therefore to social welfare calculations, but direct social costs typically feature more prominently. By contrast, this section will focus on a few implications for deterrence of choosing between different types of criminal sanctions.

While attractive on the grounds that they are less socially costly than other types of sanctions, monetary sanctions often face an essential practical difficulty: offenders often, if not usually, have too few assets for the optimal fine to be imposed (Piehl and Williams 2011, p. 117). When this is the case, often with respect to serious crimes, fines will underdeter relative to other sanctions. As the saying goes, “you can’t get blood from a stone”; the actual scope of punishment is therefore limited to what can reasonably be extracted from an offender. By definition (or at least the assumption is that), courts and corrections departments are unable to force a person to work (else, the fine becomes nonmonetary). In the limit, if a potential offender has no assets whatsoever and no realistic prospect of acquiring (or incentive to acquire) assets in the future that can be made subject to attachment, fines will produce no deterrence. Furthermore, once assets are exhausted, marginal deterrence is absent, also.

Technically, all sanctions have this feature. For instance, we only have so much time to live, and so a threat of incarceration will fail to deter someone who is certain he will die in the next 24 hours. But there are important reasons why the average potential offender’s circumstances are more likely to allow him to avoid (and know he can avoid) a monetary sanction. First, although not an iron law, most potential offenders are financially insecure. Indeed, in the case of crimes with a financial motive, the source of the benefit of the crime may be the offender’s lack of assets or alternative options for earning a living. Second, most potential offenders are comparatively young, which means that even if they have no financial resources, they

have other assets—years of their lives—that will serve as a better foundation on which to base a sanction. One can compensate for the limited assets of offenders by increasing the likelihood that any crime is detected, but this is a costly response and is insufficient when adequate deterrence requires a high fine.

Monetary sanctions—or at least significant ones—may also differ in other key ways from nonmonetary sanctions. Most importantly, levels of risk aversion—central in identifying deterrence model predictions—will almost certainly differ depending on whether the potential offender faces fines or nonmonetary sanctions. There is little evidence in support of the idea that potential offenders will be risk loving with respect to an increase in a threatened fine, whereas offenders may anticipate becoming accustomed to long imprisonment after so many years, increasing their relative preference for risk (Shavell 2004, pp. 503 n.17, 508).

Fines also differ from other forms of criminal sanctions in how potential offenders perceive them. Piehl and Williams (2011, p. 116) suggest that fines are viewed as “softer” than other forms of punishment—perhaps just a price, one that is not often paid—and that potential offenders’ responses to fines relative to other sanctions will be heterogeneous. Briefly stepping outside of the neoclassical economic framework, cognitive and behavioral biases clearly play an important role in distinguishing types of sanctions in the minds of offenders. Also worth noting is the fact that a monetary fine may be easier to set optimally when the crime is one that results in a financial benefit for the offender or a financial harm to a victim, as the fine imposed can be explicitly linked to these values.

Modern nonmonetary sanctions as a group tend to involve (1) constraints on where an offender can go, what he can do, who he can see, or where he can live (e.g., incarceration, residency restrictions, or banishment), (2) affirmative obligations that require time and effort (e.g., registration requirements), or (3) the imposition of psychic harm, usually through some form of humiliation (e.g., shaming penalties generally or sex offender community notification requirements). Of the possible nonmonetary sanctions, intermediate or alternative

sanctions—which were defined above—appear to be increasingly attractive from the government’s perspective because they are less costly than incarceration, because they do not require that an offender has wealth or income (Miceli 2009, p. 279), and because technological innovation offers the potential to reclaim otherwise forgone incapacitation benefits. At the same time, there are good reasons to surmise that offenders will perceive these sanctions in very different ways and that the effective cost of these sanctions to the offender will depend on characteristics more difficult to measure than the financial assets or wages of the offender.

Moreover, these sanctions, especially intermediate or alternative sanctions, may generate deterrence using more complicated mechanisms. For instance, relative to fines, we know incarceration may work differently across the board and with respect to specific people: a different asset (opportunities during a period of time) is confiscated from the offender, but money is typically easier to value and to relate to how the offender benefits from committing the crime or the social harm the crime caused. On the whole, though, all sanction types, if set appropriately and with an eye toward these concerns, should be capable of playing the generic role of *s*, shifting the perceived cost of committing a crime in a way that may cause the offender to use his time differently.

Nevertheless, there are at least two important reasons for explicitly considering the specific roles that the various types of criminal sanctions might play in any model of offending behavior, both of which can add to our understanding of criminal deterrence generally.

First, as pointed out at the end of the discussion of the types of criminal sanctions, the *simultaneous* use of two or more different kinds of sanctions may generate different deterrent effects than a comparable amount of punishment using a single sanction type. (Note: This proposition is distinct from the result from the public enforcement literature that an optimal sanction scheme involves first exhausting wealth through fines before turning to nonmonetary sanctions. This well-known idea turns on fines being superior but limited by the liquidity constraints of the offender.) Prescott and

Rockoff (2011) find evidence consistent with this idea in the sex offender law context, reporting surprisingly strong deterrent effects from the addition of post-release notification requirements (effectively, shaming) to be imposed at the end of already very long sentences. Although comparing the two is complicated, research that has examined simply the addition of more prison time at the end of a long sentence appears to suggest that “more of the same” had weaker effects (Kessler and Levitt 1999).

If there are diseconomies of scale or perhaps economies of scope in the deterrent effects of criminal sanctions, one likely mechanism is that offenders perceive the sanction regimes differently: adding distinct sanctions may seem worse than simply adding more of a sanction already in play. It is also possible that increasing the severity of punishment by adding a new type of sanction does not invite additional risk taking by offenders who are risk lovers, allowing the reduction in criminal activity by the risk averse to more clearly dominate the final deterrence tally.

Second, even if two criminal sanctions are thought to be equivalent in terms of their *deterrent* effects from the perspective of a potential offender, criminal sanctions may differ in how they influence ex post offender behavior down the road, leading potentially to different criminal activity levels in the aggregate. For example, the use of incarceration not only deters potential offenders ex ante but it incapacitates those who do choose to offend, which may offer separate social value in precluding subsequent offenses. There is no a priori reason to think that these indirect effects are always positive nor that they function solely in ways unrelated to deterrence.

Indeed, collateral effects of criminal sanctions may have indirect consequences for deterrence itself—and they may in fact *encourage* offending. Sex offender notification laws, for example, are intended to reproduce an upside of incarceration, essentially incapacitating potential recidivists by using information to aid potential victims in creating a barrier between themselves and released sex offenders. Unfortunately, notification also produces many deprivations in addition to the

incapacitation effect: finding employment and housing are difficult, public shaming results in strained relationships, and so on. Furthermore, these deprivations do not depend on whether the offender engages in criminal behavior. As a result, although the threat of notification may deter criminal offending ex ante by raising the costs of committing a sex crime, the application of the requirements ex post may hamper deterrence, by reducing the relative benefits of staying on the straight and narrow (Prescott and Rockoff 2011). Unless the incapacitation effect more than offsets this reduction in deterrence (or if notification increases p sufficiently through additional contact with law enforcement or public monitoring), criminal activity should increase, all else equal.

Empirical Evidence on Deterrence

There is a substantial and growing body of empirical evidence on criminal deterrence, and this entry only offers a brief summary of this research. For recent and detailed discussions of key papers and open questions, see generally Nagin (2013), Durlauf and Nagin (2011), Levitt and Miles (2007), Robinson and Darley (2004), Eide (2000), and Freeman (1999). Recognizing that empirical work must study changes from an existing framework of criminal sanctions and enforcement levels and that there is no reason to think deterrent effects should be homogeneous across the different departure points, much less across all types of crime, types of sanctions, and sanction levels, the work is decidedly mixed. Notwithstanding these caveats and all of the others implicit in empirical work in general, some basic points of conventional wisdom have emerged.

First, as a general matter, most scholars interpret the literature as strongly supporting the ability of criminal sanctions and enforcement to deter criminal behavior. The evidence in favor of “substantial” deterrent effects across “a range of contexts,” according to some, is “overwhelming” (Durlauf and Nagin 2011, p. 43). The details, however, reveal quite a bit of variation (in magnitudes, in particular), and others strongly disagree with this general conclusion—at least in

terms of the policy implication that an increase in s or p from present levels would result in less crime—on the basis of alternative evidence that appears inconsistent with it (like evidence that suggests many offenders are unaware of the size of criminal sanctions) and methodological objections (see, e.g., Robinson and Darley 2004), which are particularly strong with respect to early work and which are discussed in most reviews. Eide (2000, pp. 364–368) also highlights the importance of properly interpreting the empirical evidence.

Second, most scholars agree that increasing the degree of enforcement (p) (often referred to as “certainty” in the literature) appears to be more effective than a comparable increase in the severity of sanctions, at least given the current levels of each. Consistent with the models of Schmidt and Witte (1984, p. 160), Nagin (2013, p. 201) concludes that the evidence in favor of certainty is much stronger with respect to the probability of arrest and less so (or at least with more uncertainty) with respect to conviction and other later conditional enforcement probabilities. To the extent that deterrence is an important goal of criminal law, the take-away from these patterns is that crime policy should focus on how laws are enforced rather than on the severity of sanctions.

Third, all agree not only that increasing the severity of sanctions appears less effective than increasing the degree of enforcement but also that there is still some question whether, at current sanction levels, increasing severity will result in *any* reduction in crime (Durlauf and Nagin 2011). Studies of the effects of increased severity on crime are much more likely to produce estimates that are not statistically significant, and at times, the estimates are even positive (Eide 2000, p. 360). This body of work is actually remarkably consistent with what one would have expected to find given the conclusions of the theoretical work. In the standard models of criminal behavior, increasing sanction severity, for instance, was more likely to lead to more crime all else equal than increasing the certainty of enforcement, especially to the extent that the offenders in question are risk loving.

Concluding Remarks

The goal of this entry has been to contextualize the law and economics of criminal deterrence by linking research in economics to the range of criminal sanctions that exist in the real world. Some emphasis has been placed on the role intermediate or alternative sanctions might play in the deterrence framework, as there appears to be very little theoretical work on the subject. Unfortunately, many basic ideas from the research on deterrence are not reviewed in this entry. Optimal enforcement policy has only been mentioned in passing, and many key ideas in the deterrence literature have been omitted: marginal deterrence (see Shavell 2004, p. 518), specific deterrence (see Shavell 2004, p. 516), the roles that can be played by a fault standard or affirmative defenses in designing sanctions (see Shavell 2004, pp. 476, 494–495), and how best to deter repeat offenders (see Polinsky and Shavell 2007, p. 438).

Custodian Liability

Jef De Mot¹ and Louis Visscher²

¹Postdoctoral Researcher FWO, Faculty of Law, University of Ghent, Belgium

²Rotterdam Institute of Law and Economics (RILE), Erasmus School of Law, Erasmus University Rotterdam, Rotterdam, The Netherlands

Definition

Liability of a person for losses caused by an object under that person’s control.

The Law on Custodian Liability

Custodian liability means that a person is liable for losses caused by an object under that person’s control. It has its origins in the French law (Wagner 2012). Article 1384(1) of the French Code Civil states that a person is responsible for the damage caused by things in his custody. Originally, this phrase was not intended as a separate cause of action but merely as a reference to the provisions 1385 and 1386 CC, which respectively hold keepers of animals and owners of buildings liable for damage caused by animals or defective buildings. Some landmark judgments by the Cour de Cassation however transformed this statement into the legal basis for making custodians liable for damages caused by objects of *any kind*. A claimant needs to show that the thing has contributed to the realization of the damage. A thing includes all inanimate objects. It can be dangerous or not dangerous, movable or immovable (e.g., a lift, a dyke), natural or artificial, and defective or nondefective. The contribution of the thing can be established in several ways (Fabre-Magnan 2010). If there has been contact between the claimant or his property and a *moving* thing (e.g., a falling tree or a rolling stone), it is simply assumed that the thing has contributed to the realization of the damage. The claimant does not need to show that the custodian contributed to the action of the thing. If there was contact between the claimant or his property and a *nonmoving* thing, the claimant needs to prove that the thing was instrumental in causing the damage in some way. He can do this by showing that the thing behaved in an abnormal way, more particularly that the thing was defective or was in an abnormal position. Finally, if there was no contact between the claimant or his property and the thing, Art. 1384(1) may apply, but the claimant needs to prove that the thing was the cause of his damage. The liable person in Article 1384(1) is the *custodian*: the person who had, at the time of the accident, the power to use, control, and direct the thing. Often this will be the owner of the thing, but also people other than the owner can be the custodian. The custodian can escape liability if he can prove an external cause of the damage which was both unforeseeable and unavoidable. The external cause

can be due to *force majeure*, the act of a third part or the act of the victim. This defense is generally rather difficult to prove. Also, the custodian can invoke the claimant's contributory negligence. If successful, the amount of compensation the custodian needs to pay is reduced.

Many legal systems that have adopted or integrated the French Code Civil have been influenced by the French model of custodian liability (Wagner 2012). The concept of custodian liability is known in, for example, Italy, Portugal, the Netherlands, Belgium, and Luxembourg. One important exception is Spain. Custodian liability is also unknown in German law, English common law, and more generally in countries outside the gravitational force of the Code Civil. Some countries which have introduced custodian liability limit this concept to cases where the object suffers from a defect (e.g., the Netherlands and Belgium). It is a general requirement that the object in question represents a source of abnormal danger to its surroundings. Case law in this respect frequently refers to the normal expectations in society with respect to the characteristics of the object.

The remainder of this contribution is structured as follows. Section “[Advantages of Strict Liability and Negligence in the Context of Liability for Harm Caused by Objects](#)” briefly discusses the relative advantages of strict liability and negligence for damage caused by objects under a person's control. Section “[Economic Analysis of Case Law on Custodian Liability](#)” provides an overview of how some European countries have actually applied the several concepts of custodian liability in an economically efficient way. Section “[Conclusion](#)” concludes.

Advantages of Strict Liability and Negligence in the Context of Liability for Harm Caused by Objects

Should custodian liability be an application of strict liability or negligence? In this section, we provide a brief overview of the main relative advantages of both rules (also see Schäfer and Müller-Langer 2009, pp. 3–45). There can be sound economic reasons to hold the custodian

strictly liable for losses caused by an object under his control:

- It provides incentives to the liable party to maintain his things, to regularly check and if necessary repair them, to replace components, etc.. In theory, negligence could also provide those incentives, but then the victim has to prove that the custodian did not take enough care and that he should have known about the existence of a defect. This will often be very difficult since many care measures may be non-verifiable (e.g., how often did the injurer check the brakes of his bicycle). Negligence would therefore frequently not result in liability and the behavioral incentives of liability would be frustrated. Therefore, the superior information of the custodian regarding which care measures he actually *has taken* pleads for strict liability. Especially with respect to immovables, the custodian will generally be better informed about the quality of the building or structure and about the care measures that are taken and that can be taken.
- Negligence can only give care incentives to the injurer in the dimensions that are incorporated in the negligence rule. Strict liability gives the injurer care incentives also in non-verifiable dimensions, which cannot be incorporated in a behavioral norm. On the other hand, when it is more important to provide care incentives in all dimensions to the victim rather than to the injurer, negligence is to be preferred: only then will the victim (being the residual loss bearer) receive care incentives in all dimensions.
- Similarly, strict liability is preferable when it is more important to control the activity level of the custodian than that of the victim (Shavell 1980, p. 2; Landes and Posner 1987, p. 61; Faure 2002, p. 366; Posner 2003, pp. 177, 178; Shavell 2004, p. 193). Many accidents can be regarded as unilateral because the victim has no influence on their incidence. In bilateral cases, where also the victim should take care, a defense of contributory or comparative negligence is necessary under strict liability to avoid that the victim takes no care at all because the injurer would be liable anyway.

- If the injurer has better information than the courts regarding which care measures he *can* take and what the costs and benefits of such measures are, strict liability is to be preferred. There the injurer himself weighs costs and benefits of care, whereas under negligence the court has to do that (Shavell 2004, pp. 18, 188; Landes and Posner 1987, p. 65).
- According to many law and economics scholars, the problem of judgment proofness is more severe under strict liability because the “reward” for being careful (reducing the accident probability) is lower than under negligence (fully escaping liability). Taking care under negligence is therefore also worthwhile for lower levels of wealth.
- If the injurer is a firm, strict liability induces loss spreading via the price of the product/service, whereas negligence leaves the loss (concentrated) with the victim.
- Insurance issues such as moral hazard and adverse selection often give a preference for negligence. Especially in situations which could be regarded as unilateral, an insured victim cannot display moral hazard, whereas an insured injurer could (Bishop 1983, p. 260; Faure 2005, p. 245, 261). In as far as liability insurance makes use of experience-rated premiums, deductibles, etc., the relative importance of this issue may be limited.
- Finally, administrative costs are generally assumed to be lower under strict liability, especially because more settlements are expected (there is no dispute over the true and due levels of care).

Economic Analysis of Case Law on Custodian Liability

De Mot and Visscher (2014) argue that Dutch and Belgian courts apply custodian liability in an economically efficient way (full references to the cases mentioned in this chapter can be found in De Mot and Visscher (2014)). First, the courts use the concept of defect to allocate costs to the least cost avoider. Courts often conclude that there is a defect when it is more important to provide

incentives to the injurer to take (often) unverifiable precautions and that there is no defect when it is more important to provide incentives to the victim to take such precautions. This way, the accident losses are allocated to the “least cost avoider.” This is especially clear in cases where the floor of a shop becomes slippery (or more dangerous) due to something laying on the floor, e.g., a vegetable leaf in the vegetable department of a supermarket. According to Belgian and Dutch courts, the mere presence of the leaf does not make the building defective. In a Dutch case, the court first noted that the floor is cleaned every morning, that there is always personnel present which is instructed to pick up litter if they observe it, and that there is active monitoring on littering. These measures are relatively easy to verify. What is much more difficult to verify is (1) whether the personnel always picks up litter when they observe it and (2) how careful the client walks in the shop. So the question becomes: if we can only give one party incentives to engage in non-verifiable measures, who do we choose to incentivize? Which party’s non-verifiable measures are most productive? Given that it is unreasonable (read: too costly) to require the shop to keep the floor clean all the time, clients have to realize that vegetable leaves (or comparable litter) may lie on the floor. It is thus important that clients are prudent. They are the least cost avoiders (with respect to the non-verifiable precautions). A comparable decision has been taken in Belgian and Dutch cases where someone slipped on the floor of a supermarket near the entrance which was wet due to the rainy weather and soaked carpets. Again, it is more difficult for the supermarket to avoid the floor from becoming wet and slippery also in situations of rain than it is for individuals to walk carefully in situations where the water and dirt were clearly visible. As the Belgian court stated: “During rainy weather, it is impossible for a supermarket to make sure the floor is dry continuously.” Furthermore, in cases in which the courts decided that there actually *was* a defect, it is clear that the customer was *not* the least cost avoider. The courts, for example, decided that the supermarket floor was defective in the following cases: ice cream on the floor of

the perfume department, oil on the floor of the food department, and a vegetable leaf on the floor in the textile department. Customers do not expect ice cream in the perfume department or vegetable leaves in the textile department, and they cannot be the least cost avoider. The shop owner is better placed to instruct his personnel to be watchful. As the court stated in the case of oil on the floor of the food department: “the (lower) court could lawfully decide that the floor of the food department was defective by establishing that the floor was exceptionally slippery due to an oil stain which was difficult to observe for a normally attentive customer and that an oil stain in this department is not an everyday phenomenon which clients reasonably have to expect and avoid.” De Mot and Visscher (2014) discuss many other slip and fall cases (e.g., a woman tripping over a gasoline hose at a gasoline station, a customer slipping over French fries in a chips shop, a bicyclist slipping when crossing wet train tracks) and other types of cases (e.g., a man ordering pheasant in a restaurant and damaging his teeth because there was still some lead in the pheasant, a shed catching fire while welding work was executed there) in which the courts make their decision in an economically efficient way.

Second, in some cases the discussion is not about whether the object is defective, but there is disagreement over who is the custodian. In these cases, the courts fill in the *concept of custodian* as if they place liability on the least cost avoider. For example, a player of a sports club got injured due to an iron bar sticking out from the field but hidden under the grass. The sports club had permission from the renter of the field to use the field for a couple of hours. The Belgian court concluded that the renter and not the owner of the field or the sports club was the custodian of the sports field, since the renter was the party who “called the shots” and took all the factual decisions with respect to the field; the sports club was only permitted to use the field after permission of the renter and only for a couple of hours and in the condition that the field was in. Hence, the renter was better placed to prevent the accident than the owner or the sports club. In a Dutch case, the victim fell off a stairway to the basement. He

was an employee of a telecom company who had to repair a connection in a shop, which was located at the top of a stairway. The employee walked down the stairway because the lid of the connection point was missing, and he wanted to check if it had fallen onto the basement floor. The fore-last step of the stairway turned out to be missing and the employee fell down the stairway. The court holds the renter of the building, who operated his shop there, strictly liable because there was a step missing and there was no adequate warning against this danger. The renter argued that the owner of the building should be held liable, but the court applies Art. 6:181 CC, which states that the business user rather than the possessor is the liable party. This makes economic sense: the renter of a building uses the building on a daily basis and is better informed about possible risks (such as a missing step) than the owner, who might not enter his rented building for substantial periods of time. It is therefore better to incentivize the renter to use his superior information (either by repairing the problem himself or by informing the owner that he should repair the stairway) than to require the owner to regularly check his buildings in which another party operates his business. More generally, in cases in which it is debated whether the letter or the renter was the custodian, Belgian courts have taken into account some elements that can obviously be linked to the least-cost-avoider concept. The following elements make it more likely that the letter is the custodian and not the renter (see Vansweevelt and Weyts (2009), pp. 485–487): limits on the use of the object for the renter (the object can only be used for a limited period, for a specific goal, or in a certain area), whether the letter is present when the object is used and whether the letter is responsible for the maintenance of the object. These considerations make economic sense. When one or more of these conditions is fulfilled, it is more likely that the letter and not the renter is the least cost avoider.

Conclusion

Economic analysis of tort law has shown under which circumstances strict liability creates better

incentives than negligence and vice versa. Often, whole classes of cases in which strict liability should apply can be described in a rather simple way (e.g., for transporting and/or working with dangerous substances). In other types of cases, however, like slip and fall cases, what is the optimal rule is more ambiguous. In some cases, strict liability leads to better results, and in other cases negligence is superior. In some European countries, this difficult exercise is performed by the courts through the interpretation of the concepts defect and custodian. The variety of solutions which is reached in this manner cannot be fully replicated with a binary choice between strict liability with a defense of contributory negligence and negligence with a defense of contributory negligence. If we choose a rule of strict liability with a defense of contributory negligence, we cannot reach optimal solutions in cases in which the victim's non-verifiable measures are very likely to be the most productive ones. And if we choose a rule of negligence with a defense of contributory negligence, we cannot reach optimal solutions in cases in which the injurer's non-verifiable measures are very likely to be the most productive ones. The interesting feature of the concept of a defect as it is interpreted by the Belgian and Dutch courts is that it enables the court to select the liability rule that is most suitable for the case at hand.

This field of tort law can still benefit from further economic research. For example, De Mot and Visscher (2014) have focused on Dutch and Belgian case law. Whether courts in other jurisdictions interpret the various concepts related to custodian liability in an economically efficient way is yet to be discovered. Also, it would be interesting to compare the concepts of defect and custodian with the concepts that are used in countries in which custodian liability is unknown and which may also have the effect of efficiently sorting between cases.

Customary Law

Bruce L. Benson
Department of Economics, Florida State
University, Tallahassee, FL, USA

Abstract

Customary law, a system of rules of obligation and governance processes that spontaneously evolve from the bottom up within a community, guides behavior in primitive, medieval,

and contemporary tribal societies, as well as merchant communities during the high middle ages, modern international trade, and many other historical and current settings. Rules and procedures are recognized and accepted because of trust arrangements, reciprocities, mutual insurance, and reputation mechanisms, including ostracism threats. Negotiation (contracting) generally is the most important source for initiating change in customary law. Such agreements only apply to the parties involved, but others can voluntarily adopt the change if it proves to be beneficial. An individual also may unilaterally adopt behavior that others observe, come to expect, and emulate, or a dispute may arise that results in an innovative solution offered by a third party and voluntarily adopted by others. Many different third-party dispute resolutions procedures are observed in different customary communities, but they generally involve experienced mediators or arbitrators who are highly regarded community members. Some of these adjudicators may have leadership status, but leadership arises through persuasion and leaders do not have coercive authority. Since there is no coercive authority, protection and policing rely on voluntary arrangements, and community norms encourage and reward such activity. People who violate rules are generally expected to and have incentives to compensate victims for harms. Customary law is polycentric, with hierarchical arrangements to deal with intercommunity interactions. Customary law also may conflict with authoritarian law. When this occurs, a coercive authority may attempt to assert jurisdiction over a customary-law community, but this will have very different impacts depending on the options available to members of the community. The authority often adopts and enforces some customary rules in order to avoid conflict.

Synonyms

Informal law, Polycentric law, Private law, Stateless law

Definition

Customary law: a system of rules of obligation and governance processes that spontaneously evolve from the bottom up within a community.

“Customary law” sometimes refers to various immanent principles, so well established and widely recognized that sovereigns feel obliged to adopt them as law (e.g., as in common law recognition of “immemorial custom”), but it also can be applied to the legal arrangements within primitive communities. Another definition delineates the source of immanent customary principles, however, and encompasses primitive law: customary law is a system of rules of obligation and governance processes that spontaneously evolve from the bottom up within a community (Pospisil 1971). This definition is the focus of the following presentation. Those who contend that “law” consists of general commands of a sovereign will not consider this concept to be appropriately labeled as law, nor will those who contend that “law” applies to moral principles, whether logically derived or handed down by a higher being. Nonetheless, these rules and processes are real, and they influence behavior in very significant ways. This is true for the primitive (Pospisil 1971; Benson 1991), medieval (Friedman 1979), and contemporary tribal societies (Benson and Siddiqui 2014), merchant communities during the high middle ages (Benson 1989, 2014), modern international trade (Benson 1989), and many other historical and current settings (Fuller 1981).

Kreps (1990) stresses that socially or culturally derived experiences help players “know” what to do and predict what other players will do. In this context, Hayek (1973, pp. 96–97) observes that many issues of “law” are not “whether the parties have abused anybody’s will, but whether their actions have conformed to expectations which other parties had reasonably formed because they corresponded to the practices on which the everyday conduct of the members of the group was based. The significance of customs here is that they give rise to expectations that guide people’s actions, and what will be regarded as binding will therefore be those practices that everybody counts on being observed and which thereby

condition the success of most activities.” Similarly, Fuller (1981, p. 213) explains that “We sometimes speak of customary law as offering an unwritten code of conduct. The word *code* is appropriate here because what is involved is not simply a negation, . . . but of this negation, the meaning it confers on foreseeable and approved actions, which then furnish a point of orientation for ongoing interactive responses.” In this light, behavioral patterns individuals within a community are generally expected to adopt and follow in their various interdependent activities are considered to be legal rules below, whether those rules (expectations) arise through formal legislation or informal customary processes discussed below. Individuals are expected to follow such rules, and these expectations influence the choices made by other individuals. Customary law involves more than rules of behavior, however, as customary governance processes also evolve from the bottom up (Benson 1989, 2011, 2014; Pospisil 1971). Development and characteristics of both customary behavioral rules and procedural rules are discussed below.

Establishing and Recognizing Customary Rules

Vanberg and Buchanan (1990, p. 18) define rules of behavior toward others which individuals have positive incentives to voluntarily recognize as “trust rules” and explain that:

By his compliance or non-compliance with trust rules, a person selectively affects specific other persons. Because compliance and non-compliance with trust rules are thus “targeted,” the possibility exists of forming cooperative clusters.... Even in an otherwise totally dishonest world, any two individuals who start to deal with each other - by keeping promises, respecting property, and so on - would fare better than their fellows because of the gains from cooperation that they would be able to realize.

Game theory demonstrates that such cooperation can arise through repeated interactions, although the dominant strategy in bilateral games still depends on expected payoffs, frequency of interaction, time horizons, and other considerations (Ridley 1996, pp. 74–75). As

North (1990, p. 15) explains, however, game theory “does not provide us with a theory of the underlying costs of transacting and how those costs are altered by different institutional structures.” For example, if bilateral relationships form in recognition of the benefits from cooperation in repeated games, and if individuals in such relationships enter into similar arrangements with other individuals, a loose knit group with intermeshing reciprocal relationships develops. As this occurs, tit for tat becomes less significant as a threat, while expected payoffs from adopting trust rules increase. For instance, an exit threat becomes credible when each individual is involved in several different games with different players, in part because the same benefits of cooperation may be available from alternative sources (Vanberg and Congelton 1992, p. 426).

When the exit option becomes viable, Vanberg and Congleton (1992, p. 421) explain that a potential strategy is unconditional cooperation unless uncooperative behavior is confronted, and then imposition of some form of explicit punishment on the noncooperative player as exit occurs. They label such a strategy “retributive morality”; examples include the “blood feuds” of tribal (Benson and Siddiqui 2014) and medieval (Friedman 1979) societies. Retributive morality strengthens the threat against noncooperative behavior relative to tit for tat. Such violence is risky, however, and there is likely to be a better alternative. Since all community members have exit options, information about uncooperative behavior can be spread, creating incentives for everyone to avoid interacting with the untrustworthy individual. This suggests a strategy involving unconditional cooperation in all interactions with other community members, along with a refusal to interact with any individual who is known to have adopted noncooperative behavior with anyone in the group and the spread of information about such behavior. Vanberg and Congleton (1992) refer to this response as “prudent morality,” and given that reputation information spreads quickly and everyone spontaneously responds to information, the result is spontaneous social ostracism. Depending in part on severity of the offenses, however, ostracism may not be

absolute. Individuals might continue interacting with someone who has misbehaved, but only if certain conditions are met to reduce risk (e.g., a bond might have to be posted). Such conditions sanction an offender by raising costs or reducing his benefits in various interactions.

Many group-wide customary rules are simply commonly shared trust rules. Others, called “solidarity rules” by Vanberg and Buchanan (1990, pp. 185–186), are expected to be followed by all members of the group. The spontaneous development of social ostracism illustrates this. Solidarity rules produce community-wide benefits (Vanberg and Buchanan 1990, p. 115), including general deterrence and others discussed below.

Changing Customary Rules

Rules and communities evolve simultaneously: the evolution of trust rules leads to the development of a web of interrelationships that become a “close-knit” community, and the evolving web of interactions and expanding opportunities for interactions in turn facilitates the evolution of more rules. If conditions change or a new opportunity is recognized, for instance, and a set of individuals decide that, for their purposes, a new behavioral obligation arrangement will support more mutual benefits, they can voluntarily agree to accept (contract to adopt) the obligations. Such new obligations only apply for the contracting parties for the term of the contract. Individuals who interact with these parties learn about their contractual innovation, however, and/or members of the community observe its results. If the results are desirable, the new rules can be rapidly emulated. Such changes are initiated without prior consent of or simultaneous recognition by any other members of the relevant community, but they can be spread through voluntary adoption. Indeed, as Fuller (1981, pp. 224–225) explains, “If we permit ourselves to think of contract law as the ‘law’ that parties themselves bring into existence by their agreement, the transition from customary law to contract law becomes a very easy one indeed.” In fact, contract and custom are tightly intertwined and often inseparable:

if problems arise which are left without verbal solution in the parties’ contract these will commonly be resolved by asking what “standard practice” is with respect to the issues. . . . In such a case it is difficult to know whether to say that . . . the parties became subject to a governing body of customary law or to say that they have by tacit agreement incorporated standard practice into the terms of the contract.

. . . [Furthermore,] . . . the parties may have conducted themselves toward one another in such a way that one can say that a tacit exchange of promises has taken place. Here the analogy between contract and customary law approaches identity. (Fuller 1981, p. 176)

Negotiation (contracting) generally is the most important source for initiating change in customary law (Fuller 1981, p. 157), although there are others. An individual may unilaterally adopt behavior that others observe, come to expect, and emulate, for instance, or a dispute may arise that results in an innovative solution offered by a third party.

If new obligations are required to deal with the new situation, transaction costs may prevent individuals from agreeing on an appropriate arrangement. Similarly, one party may believe that a particular rule applies to a situation, while another may believe that a different rule is relevant. If direct negotiation fails, a solution may still be achieved if the parties turn to arbitration or mediation. Many different third-party dispute resolution procedures are observed in different customary communities (Benson 1991, 2011, 2014), but they generally involve experienced mediators or arbitrators who are highly regarded community members. They may be paid or they may voluntarily give their time in order to enhance their reputations. Whatever the process, a potential rule may be suggested by the dispute resolution (Fuller 1981, pp. 110–111). Unlike modern common law precedent, however, the resolution only applies to the parties in the dispute. If it suggests behavior that effectively facilitates desirable interactions, the implied rule can be adopted and spread through the community.

Reciprocity and Restitution

When retributive morality dominates, unilateral exaction of punishment can be very risky, as

noted above, and generate negative spillovers for the larger community. As a result, customary rules tend to evolve to reduce revenge seeking and encourage substitution of ostracism for retribution, as suggested above, but another option also commonly arises. To understand why, note that unregulated retaliation may result in greater costs for the alleged offender than the costs generated by the offender's initial offense, leading to an escalating chain of violence. In a dynamic society, this ongoing feud consumes resources, including human life, and, therefore, dissipates wealth. In subsistence societies the loss of such wealth can be devastating, but even as wealth expands, the opportunity cost of escalating feuds is high. Some of these costs are also likely to be external. Therefore, strong incentives arise among community members to constrain retribution. Parisi (2001) explains that rules generally evolve to specify who can pursue retribution (e.g., only the victim or a member of his extended family or support group discussed below) and to set an upper bound on the harm imposed on the offender based on the harm initially inflicted on the victim. Over time, the level of retribution moves to one of symmetry, "an eye for an eye." Once the severity of punishment is generally expected to be proportional, it becomes predictable, and the transaction costs of bargaining fall because the parties can bargain over a known "commodity." If the offender is willing to pay compensation that at least offsets the value the victim places on revenge, then violence can be avoided. In fact, in many customary-law systems, offenders reestablish membership in the community when appropriate payments are made. So-called blood money becomes increasingly prevalent.

History and anthropology suggest that customary restitution rules may be quite simple or very complex. For example, the *Hebrew Bible* dictates that "When anyone, man or woman, wrongs another. . . , that person has incurred guilt which demands reparation. He shall confess the sin he has committed, make restitution in full with the addition of one fifth, and give it to the man to whom compensation is due" (*The New English Bible*, Numbers 5: 6–7). Some customary legal systems include widely recognized rules detailing

payments for virtually every type of predictable harm (e.g., Goldsmidt 1951; Benson 1991, 2011; Barton 1967). In some societies, including medieval Iceland (Friedman 1979), the payment also depends in part on whether the offender tries to hide or deny the offense. If the offender admits guilt, thereby lowering the costs of enforcement, the payment is lower. Repeat offenders are also treated differently in many restitution-based systems. In Anglo-Saxon England, for instance, an offender could "buy back the peace" on a first offense, but for some kinds of illegal acts, a second offense was not be forgiven. Such an offender becomes an outlaw with no protection, making him fair game for anyone who wanted to attack him. Restitution-based systems also account for the problem of collections from potentially "judgment-proof" offenders. Payments do not necessarily have to be monetary, for instance, as labor services or other "goods" can serve as restitution. In Anglo-Saxon England offenders had up to a year to pay large awards, and if more time was required, they become "indentured servants" until the debt was worked off (Benson 2011, p. 25; 1994).

Bargaining power may differ between individuals, leading to variance in restitution for similar harms, so not surprisingly reciprocal mutual support groups typically develop in customary-law communities. These groups may consist of family members, for instance, but they also may be based on neighborhoods, religious affiliation, ethnicity, participation in the same commercial activity, or some other factor. Such groups accept reciprocal obligations to assist each other in the pursuit of justice, although they generally have many other reciprocal expectations, including social, religious, and joint production activities. Mutual support groups also may pay the restitution to a victim for someone in the group who cannot pay immediately, so the offender is obliged to pay members of his own support group. When such groups develop surety obligations they also may purchase indentured-servitude contracts so offenders work for members of their own groups rather than for their victims.

Clearly, hardships imposed on wealthy offenders who pay a fixed restitution are less

significant than the same payment for poor offenders. Thus, restitution may require a relatively large payment by a wealthy offender, enhancing their deterrence incentives. On the other hand, if a person is diverted from earning income to pursue and prosecute an offender, the value of lost time will be much higher for an individual earning a high income than for a low-income person. Therefore, restitution payments for the same offenses may be higher for the well-to-do victim in order to induce participation in the legal process. The schedule of payments in the *wergeld* or “man price” systems in Anglo-Saxon England reflects the status of the parties involved, as do some tribal customary-law systems (Barton 1967).

Negotiation between a victim and offender may be very difficult, if not impossible, of course, without additional options. As a consequence, a customary rule often develops which requires guilty parties to express remorse or repentance, thereby reducing the costs of negotiation. Substitutes for negotiation are also attractive. A community leader or group of leaders may come forward to encourage repentance and a truce so that negotiations can occur (Benson and Siddiqui 2014). Given the potential animosity between the parties, this third party might also mediate or arbitrate the dispute, or specialists in mediation or arbitration may be called upon. The primacy of rights also changes over time, as a right to restitution supersedes the right to retaliation. In early medieval England and Iceland, and in the large number of tribal societies, victims do not have the right to exact physical punish (retributive morality) unless and until the offender refuses to accept the customary adjudication procedures and/or to pay fair restitution (Benson 2011, pp. 11–30, 1991; Friedman 1979; Pospisil 1971; Goldsmidt 1951; Barton 1967). Similarly, ostracism occurs only when an offender refuses to adjudicate or to pay restitution.

Mutual Insurance

In part, to encourage people to continue to recognize customary behavioral rules, customary-law

communities develop mutual insurance arrangements to aid individuals who find themselves in significant risk as a consequence of mistakes, unanticipated natural disasters, warfare, theft, or general bad luck. Johnsen’s (1986) analysis of the potlatch system of the Southern Kwakiutl Indians provides an insightful example. He explains that “In order to provide the incentives of would-be encroachers to recognize exclusive property rights, and thus to prevent violence, those Kwakiutl kinship groups whose fishing seasons were relatively successful transferred wealth through the potlatch system to those groups whose seasons were not successful.... Although potlatching thereby served as a form of insurance, the relevant constraint in its adoption and survival was the cost of enforcing exclusive property rights rather than simple risk aversion” (Johnsen 1986, p. 42). Sharing norms such as hospitality and potlatching are common practices in customary-law societies all over the world (Ridley 1996, pp. 114–124). Therefore, even those who may find themselves in desperate situations know that recovery is possible, so they have relatively strong incentives to live up to customary obligations.

Leadership

Customary-law communities do not have executives with coercive power to induce recognition of law. Leaders arise to facilitate various kinds of cooperation, but they lead through persuasion and example. Leadership also is conditional, with no specified terms or binding claims to loyalty. Leaders generally serve as a nexus of the voluntary relationships that dominated the internal life of a community. Therefore, a very important leadership characteristic is a reputation for making good decisions (wisdom) that benefit his followers. Anyone who acquires a leadership role is likely to be a mature, skilled individual with considerable physical ability and intellectual experience and perhaps, more importantly, someone who has a history of cooperative behavior. The importance of maturity and experience often mean that leaders are relatively old community members (elders). They earn respect (Benson

1991; Pospisil 1971), but they also must continue to earn it. Individuals who achieve leadership positions but then make decisions that turn out to be undesirable to followers lose those followers. Wisdom and respect also are not sufficient to attract substantial numbers of followers (Pospisil 1971, p. 67). A self-interested entrepreneurial leader within a close-knit community rationally chooses to pursue activities that benefited others and/or generously spreads the wealth he gains. “The way in which [leadership or social] capital is acquired and how it is used make a great difference; the [members of the community] . . . favor rich candidates who are generous and honest” (Pospisil 1971, p. 67). Indeed, in customary-law societies, the honor of being recognized as a leader is often “purchased” through repeated public displays of generosity demonstrated at occasions such as marriages. Third-party mediation or arbitration often develops in close-knit groups, as noted above, and individuals seeking recognition as leaders also may offer to help resolve disputes and provide mediation or arbitration advice free of charge (Pospisil 1971; Benson 1991). “Fair” nonviolent dispute resolution is attractive to community members because it avoids the spillover costs associated with violent dispute resolution, and it is attractive to the “suppliers” of such dispute resolution even when they are not explicitly paid, because it enhances their prestige. In other words, both generous gift and advice giving (e.g., dispute resolution) signal that the individual is wise, successful, cooperative, and trustworthy. As Ridley (1996, p. 138) puts it, such acts “scream out ‘I am an altruist; trust me.’” Leaders engage in such displays of generosity because they expect to benefit in the future through reciprocal obligations and cooperation in joint production. Since leadership positions are available to anyone who can persuade a group to accept his decisions and guidance, customary communities often have multiple leaders. Competition for followers arises, and community members may change their primary allegiances if they feel that a leader has failed to perform well or that another individual offers what appear to be superior options. Specialization among leaders also is not uncommon. A community may have one or

more individuals serving as arbitrators or mediators, and/or as religious, hunt, or war leaders, and so on.

Warriors

Joint production of mutual defense against enemies evolves if outside threats are perceived, and such threats often mean an important part of an individual’s belief system will be “a concept of them and us” (e.g., tribalism, patriotism). In fact, an external enemy can strengthen incentives for intragroup cooperation (Ridley 1996, p. 174). There is no centralized authority in a customary-law system, however, so individuals cannot be forced to become soldiers. They have to be persuaded to take on this role. This explains the incentives to propagate cultural beliefs (rules) about honor from bravery and skill in warfare in primitive and medieval communities. Members of customary-law communities facing outside threats (e.g., spouses or potential spouses of warriors, fathers and mothers of potential warriors, elders who can no longer fight) have strong incentives to encourage young males to be brave and to be skilled in combat (Benson and Siddiqui 2014). Thus, the successful warrior is honored, but he also receives many personal rewards. A warrior who backs down from a threat or who does not pursue retribution will be seen as a coward, and this generally will be the greatest fear instilled in boys and young men. The prestige associated with abilities in warfare also encourages entrepreneurial war leaders to organize attacks on enemies. After all, given the belief that some other group is made up of enemies, aggression can easily be rationalized – “the best defense is a good offense” – particularly when the expected gains exceed the expected costs.

The discussion of conflict suggests a question: why warfare rather than cooperation (negotiation, diplomacy) with outsiders. In fact, as explained below, cooperation between members of different communities is also widely observed in customary-law systems. Given the high transaction costs for multiple-community collective action, however, the benefits of

intergroup cooperation have to be high for stable cooperation to develop (e.g., high enough for warriors to refrain from aggressive acts even when very attractive opportunities to attack arise). One potentially large benefit from intergroup cooperation arises when two or more groups face the same relatively powerful enemy. In this context, however, it should be noted that terms like “alliance,” which suggest established protocol, permanence, and formality, do not describe military relationships between such communities. These cooperative activities generally are expedient combinations in which distinct and autonomous individuals and groups work toward common but limited aims. Indeed, military coalitions generally are temporary spontaneous arrangements, and they can fall apart when the common threat loses power and/or one of the groups in the coalition gain power relative to others (Benson 2006).

Conflicts between customary-law communities need not be violent. When two different commercial communities have disputes or try to capture each other’s markets, they generally do not go to war with one another. Their warriors may be lawyers who pursue objectives through adversarial adjudication processes that arise, for instance, or lobbyists who compete for political favors in an authoritarian legal system, as discussed below. Conflict is certainly not inevitable, however, if benefits of intercommunity cooperation are significant.

Polycentric Law

Customary rules and procedures often facilitate voluntary cooperative interactions such as trade between members of different customary-law communities (Benson 1988). Groups need not formally “merge” and accept a common set of rules, however, in order to achieve intercommunity cooperation on some dimensions. Individuals only have to expect each other to recognize specific rules pertaining to the types of intergroup interactions that evolve. Indeed, a “jurisdictional hierarchy” may arise wherein each group has its own rules and procedures for intra-community

relationships, while a separate more narrowly focused set of behavioral and/or procedural rules applying for intercommunity relations (Pospisil 1971; Benson 1988). For instance, intra-community recognition of rules is likely to be largely based on reciprocities, trust, and reputation, along with ostracism threats (prudent morality), while intergroup recognition may require bonding, strong surety commitments, and/or threats of retribution (retributive morality). A jurisdictional hierarchy also does not create a higher order of law, as intergroup institutions typically have no role in any community’s internal relationships. Thus, customary law is “polycentric,” with multiple parallel “local” jurisdictions, as well as overlapping jurisdictions supporting intercommunity interactions. Many intragroup rules will be common across different groups, of course, as individuals in different groups discover similar ways to deal with an issue. Emulation also will occur where differences initially exist but individuals perceive superior arrangements among other groups (Benson 1988, 1989).

Custom Versus Authority

Pospisil (1971) distinguishes between “legal” arrangements that evolve from the top down through command and coercion, which he called “authoritarian law,” and customary-law systems that evolve from the bottom up through voluntary interaction. Similarly, Hayek (1973, p. 82) distinguishes between “purpose-independent rules of conduct” that evolve from the bottom up and rules that are designed for a purpose and imposed by “rulers.” Individuals may be members of different specialized customary-law communities (e.g., diamond merchants (Bernstein 1992) or trade associations (Benson 1995), a neighborhood (Ellickson 1991), and so-called informal or underground communities (de Soto 1989)) while simultaneously being subjected to authoritarian law. Both Hayek’s and Pospisil’s distinctions suggest that customary law also may conflict with authoritarian law. Indeed, as Hayek (1973, p. 82) stresses, “the growth of the purpose-independent

rules of conduct which can produce a spontaneous order will . . . often have taken place in conflict with the aims of the rulers who tended to turn their domain into an organization proper.” When this occurs, an authority backed by coercive power may attempt to assert jurisdiction over a - customary-law community, but this will have very different impacts, depending on the options available to members of the community. If the authority is strong enough, a community might be forced to accept the commands, although new customary rules and procedures often evolve that allow a customary-law community to avoid some and perhaps most authoritarian supervision (Bernstein 1992; Benson 1995). This may involve moving “underground,” making the customary rules and procedures difficult to observe, and raising the cost of enforcement for the authority. If a customary-law community (and its wealth) is geographically mobile, however, members may simply move outside an authority’s jurisdiction. The threat to move can significantly constrain authoritarian attempts to displace a customary system (Benson 1989). A sovereign who wants to avoid an exodus may even offer to assist in enforcing the customary rules, and even explicitly codify them. Indeed, a sovereign may offer special privileges to members of a highly mobile customary community in order to capture benefits including revenues, perhaps directly from tribute or taxes, but also indirectly because of a positive impact that this community has on other less-mobile sources of wealth (e.g., land) that can more easily be controlled and taxed. If customary behavioral rules are absorbed and customary procedures atrophy, an authority may amend or replace many customary rules, although the ability to do so depends on the costs of reinvigorating customary institutions, the mobility of wealth for members of the community, and the privileges granted to the community’s members.

De Jure/De Facto Institutions

Jacek Lewkowicz and Katarzyna Metelska-Szaniawska
Faculty of Economic Sciences, University of
Warsaw, Warsaw, Poland

Abstract

Recent works in Law and Economics distinguish between the so-called *de jure* and *de facto* institutions. We define these two types of institutions, as well as indicate their place in the broad institutional system, in particular relative to the formal/informal and external/internal distinctions applied in (new) institutional economics. We also mention the possible interrelationships between *de facto* and *de jure* institutions, linking them to economic outcomes, and provide examples of *de jure/de facto* analyses in Law and Economics. Finally, we reflect on controversies and lacunas in the literature and present an outlook for future research.

Definition

Recent works in law and economics distinguish between the so-called *de jure* and *de facto* institutions. *De jure* means a state of affairs that is in accordance with the law, i.e., *de jure* institutions constitute a subclass of formal institutions and must necessarily be external in nature. *De facto* means a state of affairs that is true in fact but does not have to be officially sanctioned, i.e., *de facto* institutions may be formal or informal, as well as external or internal, provided that they are operative. *De facto* and *de jure* institutions are not antonyms; they may overlap.

Introduction

Recent works in law and economics increasingly emphasize the distinction between *de jure* and *de facto* institutions, e.g., in relation to constitutional rights and freedoms (including property rights), judicial independence, central bank independence, or the independence of regulatory agencies (e.g., Law and Versteeg 2013; Melton and Ginsburg 2014; Voigt et al. 2015; Hanretty and Koop 2013). Similarly, studies in political economy use the *de jure/de facto* distinction in reference to political power and its role for economic growth and development (e.g., Acemoglu and

Robinson 2006a, b). Such a distinction is not as common in (new) institutional economics, a major background for law and economics, where a broad body of literature exists on formal and informal institutions. Research in this field is, however, also concerned with enforcement mechanisms and recently pays particular attention to the distinct measurement of de jure and de facto institutions (e.g., Voigt 2013; Shirley 2013; Robinson 2013). This entry presents the conceptualization of de jure and de facto institutions and discusses their relevance for law and economics.

De Jure and De Facto Institutions Versus Other Classifications of Institutions

Most generally, institutions are perceived in the literature as systems of established social rules that structure social interactions (Hodgson 2006). They constrain behavior and are permanent or stable (Glaeser et al. 2004). In the words of D. C. North, they are certain “rules of the game,” i.e., “humanly devised constraints that shape interaction” (North 1990, p. 3), encompassing both formal and informal systems, as well as, importantly, enforcement mechanisms. Voigt (2013) is particularly clear in emphasizing the difference between rules per se and their enforcement. According to this approach, institutions are “commonly known rules used to structure recurrent interaction situations that are endowed with a sanctioning mechanism” (Voigt 2013, p. 5).

Several classifications of institutions exist in economics, the most popular one distinguishing between formal and informal institutions. Formal institutions are laws (including constitutions), policies, regulations, rights, etc. that are enforceable by official authorities (i.e., with respect to them, there exists an official sanctioning mechanism). Informal institutions are social norms, traditions, and customs that may also shape social behavior even though they are not enforced by any official authority (Berman 2013) but by means of, e.g., social control or self-enforcement. As it is unclear how formalized a rule needs to be to qualify as a formal one, in response to this

important caveat of the formal/informal distinction, Voigt (2013) proposed another classification of institutions, i.e., internal and external institutions distinguished based on the underlying enforcement mechanism. According to this approach, when sanctioning is privately organized (i.e., by members of the group or society within which a given institution functions), the institution is internal, and when sanctioning is public, it is classified as external.

As mentioned earlier, recently a new classification of de jure/de facto institutions has emerged and becomes increasingly popular in economics and other social sciences (see, e.g., Voigt 2013; Lewkowicz and Metelska-Szaniawska 2016). De jure stands for a state of affairs that is in accordance with the law. Classical works define the law as a “rule laid down for the guidance of an intelligent being by an intelligent being having power over him” (Austin 1885, p. 86) or a “rule of conduct, prescribed by the supreme power in a state, commanding what is right and prohibiting what is wrong” (Blackstone 1979, p. 44). Being a type of norms, legal norms are “generally accepted, sanctioned prescriptions for, or prohibitions against, others’ behavior, belief, or feeling, i.e. what others ought to do, believe, feel – or else. . .” (Morris 1956, p. 610) and always include sanctions. De jure institutions are, therefore, formal and external institutions. However, as the broadest approach to institutions adopted here also encompasses formal rules governing the functioning of organizations as well as formal policies which, as such, need not be rooted in the legal system (i.e., formal policy documents may exist that are sources of constraints shaping interaction but lack the status of law), de jure institutions are a subclass of formal institutions. While the set of de jure institutions covers the entire set of external institutions (i.e., a de jure institution must necessarily be external), it may also be that a given (de jure) institution has both an external and an internal nature (i.e., the same institution is sanctioned by the state, as well as by a social mechanism). De facto institutions are those observed in actual human interactions – in the market and social practice. While fulfilling the condition of being actually operative (effective),

de facto institutions may be of varying nature – formal or informal. The enforcement mechanism behind the factual operation of these institutions may be both private and public, i.e., these institutions may be both of an internal and an external type.

De jure and de facto institutions are clearly not antonyms. Figure 1 presents the different classifications of institutions. Part (a) focuses on formal, informal, de jure, and de facto institutions. The sets of formal and informal institutions are disjoint, and together they form the complete set of existing institutions. As argued earlier, de jure institutions constitute a subclass of formal institutions. De facto institutions, in turn, may be either formal (de jure) or informal, provided that they are operative. A subclass of de jure institutions that

are perfectly enforced will simultaneously constitute de facto institutions. In effect, the de jure/de facto distinction produces sets with an overlap which do not cover the entire spectrum of institutions, i.e., there exist both formal and informal institutions which are neither de jure nor de facto, such as unenforced policies based on documents which are not law (formal) or normative beliefs when conceived as social norms (informal).

Part (b) of Fig. 1 presents the sets of external, internal, de jure, and de facto institutions. The set of de jure institutions is identical to the set of external institutions, including the latter’s intersection with the set of internal institutions. De facto institutions cover part of the de jure institutions set (including institutions of solely external

(a) sets of formal, informal , *de jure* and *de facto* institutions

(b) sets of external, internal, *de jure* and *de facto* institutions

(c) sets of formal, informal , external and internal institutions

De Jure/De Facto Institutions, Fig. 1 Classifications of institutions. (a) Sets of formal, informal, de jure, and de facto institutions. (b) Sets of external, internal, de jure, and de facto

institutions. (c) Sets of formal, informal, external, and internal institutions (Source: own elaboration)

nature, as well as those being at the same time external and internal) and part of the internal institutions set. While some *de jure* (external institutions) are neither *de facto* nor internal ones, we can also identify institutions that qualify as external, *de jure* and *de facto*, or even external, internal, *de jure* and *de facto*, at the same time.

Finally, part (c) of Fig. 1 demonstrates the relative positions of the sets of formal, informal, internal, and external institutions. While the sets of formal and external institutions are nearly identical, this is not the case for informal and internal institutions. The latter set intersects with the set of formal institutions covering those institutions which, as argued earlier, have both an external and an internal nature. Furthermore, as internal institutions include formal private rules, the set of internal institutions also expands beyond the informal institutions set.

Interrelationships Between De Jure and De Facto Institutions

Institutions usually interplay with each other. De jure and de facto institutions may boost each other when they lead to commonly desired behavior or inhibit each other when this is not the case. In dynamic settings convergence and divergence may be observed, as well as a crowding out effect between de jure and de facto institutions. Economic effects of the interrelationships between these institutions result, depending on their nature, in decreasing or increasing the level of transaction costs connected with implementing and enforcing legislation. They may also affect the aims that the legislator strives to achieve by imposing new laws, as well as government's credibility vis-à-vis economic actors.

De Jure and De Facto Institutions in Law and Economics

Analysis of the interrelationships between de facto and de jure institutions is present primarily in studies confined to individual rules. Judicial independence is an area where this distinction

has been most pronounced in law and economics over the recent years, in particular since Feld and Voigt (2003) proposed distinct measures of de jure and de facto judicial independence and provided empirical evidence confirming the relevance of the de facto, not de jure, measure for economic growth (a finding later confirmed by Voigt et al. 2015). Much debate arose in the literature concerning the relationships between de jure and de facto judicial independence, with some studies finding no relationship and others – a tight correlation (see, e.g., Herron and Randazzo 2003; Hayo and Voigt 2007). Melton and Ginsburg (2014) summarized this literature and offered an explanation, which de jure protections actually enhance de facto judicial independence. The de jure/de facto distinction has also been applied in studies focusing on independence of central banks (e.g., Hayo and Voigt 2008), prosecutors (Aaken et al. 2010), and regulatory agencies (e.g., Hanretty and Koop 2013). Other examples of institutions that have been studied with regard for the de jure/de facto distinction are, inter alia, competition policy (Voigt 2009) and direct democracy mechanisms (Blume et al. 2009).

A second area of law and economics research, where the focus has been on the de jure/de facto distinction, concerns protection of rights. Some studies have focused on explaining the determinants and/or effects of the de jure de facto gap for various categories of constitutional rights and freedoms (e.g., Law and Versteeg 2013), while others concentrated on disentangling the relationships between de jure and de facto rights (e.g., Melton 2013; Chilton and Versteeg 2016). Other types of rights analyzed from the de jure/de facto perspective are property (land) rights and the related problem of natural resource management (Robbins 2000; Alston and Mueller 2007; Alston et al. 2012; Bellemare 2013).

Future Outlook

Until recently there only existed rare empirical studies of de jure/de facto institutions, confined to individual rules, with no commonly accepted definitions and no general-level analysis of

relationships between these two types of institutions. In recent years this topic raised increased interest leading to conceptualization and a more systematic analysis from an economic perspective. This may serve as a theoretical underpinning for subsequent empirical studies, focusing on other law and economics contexts, beyond independence and rights. The discussion concerning identification of de facto institutions (i.e., ascertaining when an institution can be deemed operative/effective) will also certainly intensify alongside the stimulating debate on measurement of institutions. Another significant extension could concentrate on providing a detailed dynamic account of the interrelationships between de jure and de facto institutions. Such studies are of high policy relevance as they yield recommendations on the design of more effective legal institutions.

Death Penalty

John J. Donohue III

Stanford Law School and National Bureau of
Economic Research, Stanford, CA, USA

Abstract

The issue of the death penalty has been an area of enormous academic and political ferment in the United States over the last 40 years, with the country flirting with abolition in the 1970s, followed by a period of renewed use of the death penalty and then a period of retrenchment, reflected in a declining number of death sentences and executions and a recent trend leading six states to abolish the death penalty in the last 6 years. Internationally, there is a steady movement away from the death penalty, which has been abolished throughout the European Union, although certain states in the Middle East (Saudi Arabia, Iran) and Asia (China, Singapore, Japan) have continued to use it frequently.

Definition

A system of punishment involving the execution of individuals convicted of a capital crime.

Introduction

Death penalty statutes vary some across the 32 states with current enforceable statutes in the United States, but capital punishment is universally reserved for a relatively narrow category of “first-degree” murders that involve one or more aggravating circumstances. These aggravating circumstances typically include murdering a police officer or witness, murder for hire, multiple murders, and murders that are “heinous, atrocious, or cruel.” Even cases that are initially treated as capital eligible are very unlikely to result in a death sentence; defendants often plead guilty in return for receiving a noncapital

sentence, some defendants are found guilty of a lesser charge in jury trials, and some juries decide not to impose the death sentence even when the law would permit them to do so (National Research Council 2012).

This entry will review some of the major social science studies evaluating the issue of whether the death penalty deters, which have largely failed to provide any convincing evidence of deterrence, as well as the major studies exploring racial bias in the administration of the death penalty.

Procedural Issues Associated with the Death Penalty

The modern death penalty era in the United States began in 1972 with *Furman v. Georgia* (408 U.S. 238 1972). In that case, the US Supreme Court was concerned that the unchanneled discretion of prosecutors, judges, and juries led to the arbitrary administration of the death penalty. As a result, the Court struck down every then-existing sentence of death, stating “that the imposition and carrying out of the death penalty in these cases constitute cruel and unusual punishment in violation of the Eighth and Fourteenth Amendments.” While the Justices apparently believed that their decision would lead to the abolition of the death penalty, it ironically propelled its strong revival.

Most states, including some that had not had the penalty before, responded to *Furman* by enacting specific death penalty statutes that were designed to address the Court’s articulated concerns, including the implementation of a pretrial capital hearing along with separate guilt and sentencing trials; the consideration of so-called aggravating and mitigating circumstances that enhance or undermine the case for execution, respectively; and the automatic appeal of death sentencing decisions. Four years later, in *Gregg v. Georgia* (428 U.S. 153, 169 1976), the Supreme Court held that “the punishment of death does not invariably violate the Constitution” and indicated that several of these new statutes were facially constitutional.

However, there is a substantial and growing body of evidence that challenges the notion that the procedural changes that were deemed facially constitutional in *Gregg* have adequately addressed the concerns of *Furman* in practice. Indeed, in October 2009, the American Law Institute (ALI) voted overwhelmingly to withdraw its death penalty framework from the Model Penal Code because that framework had proved to be woefully inadequate in application (Liebman 2009). The April 15, 2009, “Report of the Council to the Membership of the American Law Institute On the Matter of the Death Penalty” expressed concerns over the inability to avoid the arbitrary, discriminatory, or simply erroneous invocation of this irrevocable punishment. These difficulties are compounded by the need to construct a system that, on the one hand, allows for consistent sentencing outcomes but simultaneously gives the fact finder sufficient leeway to consider the circumstances surrounding each crime.

Despite concerns about the administration of the death penalty, it has been broadly popular in the United States, especially during periods such as the late 1980s and early 1990s when crime in the United States was particularly high. As a result, politicians such as New York Governor Mario Cuomo failed to win reelection in part due to their opposition to the death penalty, while other governors, such as George W. Bush of Texas, were launched into national prominence because of their strong support for the death penalty.

Deterrence and the Death Penalty

The simplest law and economics assessment would suggest that the death penalty should deter murder, as it enhances the maximum penalty associated with killings. It is now recognized that this simple theoretical analysis is inadequate. First, capital punishment is invoked rarely and after years of delay due to the post-*Furman* implementation of long and complicated legal procedures that must be exhausted before any death sentence can be administered, thereby undercutting any deterrent potential. Second, the costs of

running a death penalty system are staggering, and any attempt to estimate the effect of capital punishment on crime must also take into account the fact that implementing a capital punishment system may draw resources away from other more effective law enforcement projects. A recent study from California estimated that the state’s system for prosecuting death penalty cases cost taxpayers \$4 billion between 1976 and early 2011, even though only 13 executions were carried out over the same time period (Alercon and Mitchell 2011). Cook (2009) similarly concluded that North Carolina’s execution system costs \$11 million annually, while a regression analysis performed using Maryland case data calculated that the full array of added expenses associated with pursuing a capital prosecution rather than a non-capital trial was approximately \$1 million (Roman et al. 2009).

The former Manhattan District Attorney Robert Morgenthau spoke out eloquently about the “terrible price” inflicted by the presence of capital punishment in the hopes that his words might forestall New York’s 1995 launch of a death penalty system:

Some crimes are so depraved that execution might seem just. But even in the impossible event that a statute could be written and applied so wisely that it would reach only those cases, the price would still be too high.

It has long been argued, with statistical support, that by their brutalizing and dehumanizing effect on society, executions cause more murders than they prevent. “After every instance in which the law violates the sanctity of human life, that life is held less sacred by the community among whom the outrage is perpetrated.”¹ (Morgenthau 1995)

When the New York death penalty law was adopted over Morgenthau’s opposition, he simply refused to seek the death penalty in the borough of Manhattan, as did his fellow District Attorney in the Bronx. From the implementation of the New York death penalty law in 1995 until 2004 (when it was judicially abolished), the murder rate

¹Quote is from Robert Rantool Jr. in 1846. Titus J. (1848) Reports and Addresses Upon the Subject of Capital Punishment. New York State Society for the Abolition of Capital Punishment. pg. 48.

dropped in Manhattan by 64.4% (from 16.3 to 5.8 murders per 100,000) and in the Bronx by 63.9% (from 25.1 to 9.1 per 100,000). Another New York City borough with the same laws and police force and with broadly similar economic, social, and demographic features as Manhattan and the Bronx – Brooklyn – had a top prosecutor who issued the largest number of notices of intention to seek the death penalty, and yet Brooklyn experienced only a 43.3% decline in murders over this period (from 16.6 murders to 9.4 per 100,000 in 1995) (Kuziemko 2006; Donohue and Wolfers 2009). Strong causal inferences cannot be drawn from Manhattan and the Bronx's homicide decline, but this example illustrates the lack of an apparent capital punishment deterrent effect in the crime patterns across these counties.

While a steady stream of papers beginning with Ehrlich (1975) have tried to make the empirical case that the death penalty has been a deterrent to murder in the United States, these studies have largely been rejected by the academic community (National Research Council 1978; Donohue and Wolfers 2005, 2009; Kovandzic et al. 2009; National Research Council 2012). The mounting evidence undermining the view that the death penalty deters crime has begun to influence the US Supreme Court's discussion of the constitutionality of the death penalty, as illustrated by the debate between Justices Stevens and Scalia in *Baze v. Rees* (553 U.S. 35 2008). Justice Stevens agreed with the majority in that case that the cocktail of drugs used by Kentucky to execute prisoners did not violate the Eighth Amendment, but went on to argue that there was "no reliable statistical evidence that capital punishment in fact deters potential offenders."

Justice Scalia responded sharply to Justice Stevens's concurrence. Referencing an article by Cass Sunstein and Adrian Vermeule (Sunstein and Vermeule 2005), Scalia argued, "Justice Stevens' analysis barely acknowledges the 'significant body of recent evidence that capital punishment may well have a deterrent effect, possibly a quite powerful one.'" However, knowledgeable researchers believe that this so-called significant body of evidence was based on outdated or invalid econometric techniques and models. Indeed,

shortly after the decision was handed down, Sunstein indicated that he had changed positions in the wake of the scholarly demolition of the existing pro-deterrence literature, writing, "In short, the best reading of the accumulated data is that they do not establish a deterrent effect of the death penalty" (Sunstein and Wolfers 2008).

In April of 2012, a panel of the National Research Council (NRC) issued a report on deterrence and the death penalty, concluding that previous research was "not informative about whether capital punishment decreases, increases, or has no effect on homicide rates." The panel based this decision on two main factors. First, they noted that existing studies did not adequately model the effect of noncapital punishment on crime, which would bias estimates of the effect of capital punishment on crime if common factors influenced both the frequency of death sentences and the severity of noncapital punishment. To accurately capture the deterrent effect, researchers would need to show the deterrent effect of the death penalty in comparison to other common sanctions.

Second, the panel wrote that existing research did not adequately model "potential murderers' perceptions of and response to the capital punishment component of a sanction regime." The NRC panel noted that potential offenders cannot be deterred by the death penalty unless they are aware of the threat, and there is a large body of literature confirming that the general public is very poorly informed about the actual likelihood of the imposition of death penalty sentences. The NRC report also determined that many earlier studies used "strong and unverifiable assumptions" in their identification strategies (National Research Council 2012).

Racial Bias in the Implementation of the Death Penalty

There is an expansive empirical literature on whether race affects prosecutors' and jurors' death penalty decisions, with nearly all recent studies finding that race does influence capital sentencing outcomes. David Baldus's 1990 study

of capital sentencing in Georgia, *Equal Justice and the Death Penalty*, was a landmark study in the empirical evaluation of the impact of race on the administration of the death penalty. Similar studies conducted in states, counties, and cities across the United States confirm these findings, and a number of studies have used controlled experiments to pinpoint precisely how race affects capital outcomes. The results of these studies further corroborate the findings of the econometric literature: race inappropriately influences the administration of the death penalty even after controlling for legitimate case characteristics.

The Baldus Study on Capital Sentencing in Georgia

Baldus's Georgia study investigated the effect of race on decisions throughout the charging and sentencing process by analyzing a large, stratified random sample of 1,066 defendants selected from the universe of 2,484 defendants who were charged with homicide and subsequently convicted of murder or voluntary manslaughter in Georgia between March 28, 1973, and December 31, 1979. The researchers then weighted this sample, which included 127 defendants who had been sentenced to death, to evaluate the effect of race on capital sentencing in the case universe as a whole. The researchers reviewed each defendant's case files and collected data on the circumstances of the offense and the characteristics of the defendant. Using both linear probability and logit models, the Baldus team conducted an extensive regression analysis investigating the main effect of race on capital sentencing in Georgia. Eight models differing in their method and in their explanatory variables were presented, each of which indicated that victim race inappropriately influenced which defendants were sentenced to die and which were permitted to live.

This comprehensive analysis showed that defendants convicted of murdering a white victim were statistically significantly more likely to be sentenced to death than defendants convicted of murdering a black victim. A logistic regression model from this study showed that the odds of being sentenced to death were 4.3 times greater for a defendant convicted of murdering a white

victim than for a defendant convicted of murdering a black victim. This became the core piece of evidence regarding the race-of-victim discriminations in *McCleskey v. Kemp* (481 U.S. 279 1987). This difference was statistically significant at the 0.005 level. Victim race exerted a greater influence on capital sentencing outcomes than numerous legitimate factors, such as whether the offense was coupled with kidnapping, whether the victim was frail, or whether the victim was an on-duty law enforcement officer.

Baldus et al. also used two different approaches to evaluate whether death sentencing decisions were influenced by the *interaction* of the race of the defendant and the victim. First, the authors examined narrative summaries of cases that were death-eligible under the state's contemporaneous-felony statutory aggravating circumstance. This statutory aggravating factor served as rough proxy for death eligibility, because death penalties were imposed primarily in cases involving contemporaneous felonies. The researchers classified the 438 cases involving a contemporaneous felony into various crime subcategories and then compared the death sentencing rates for similar types of cases involving different combinations of defendant and victim race.

As shown in Table 1, controlling for the type of contemporaneous felony revealed that the race of the victim strongly influenced capital sentencing. The interaction between defendant and victim race was particularly pronounced for armed robbery cases, as a black defendant was over six times more likely to be sentenced to death if convicted of murdering a white victim than if convicted of murdering a black victim. The disparity between the death sentencing rates of cases involving a black defendant and white victim and cases involving a black defendant and a black victim is statistically significant at the 0.01 level. The disparity between these racial combinations is also significant at the 0.05 level for burglary and/or arson cases and the 0.01 level for armed robbery cases.

Second, the researchers employed regression techniques to examine how the race of the defendant and victim interacted to influence capital

Death Penalty, Table 1 Race of defendant/victim and death sentencing in Georgia by contemporaneous felony

Contemporaneous felony	% of cases with a <i>black</i> defendant and a <i>black</i> victim that result in a death sentence	% of cases with a <i>black</i> defendant and a <i>white</i> victim that result in a death sentence	% of cases with a <i>white</i> defendant and <i>black</i> victim that result in a death sentence	% of cases with a <i>white</i> defendant and a <i>white</i> victim that result in a death sentence	Ratio of probability of a death sentence for a black-on-white murder to probability of death sentence for a black-on- black murder (controlling for contemporaneous felony)
	(A)	(B)	(C)	(D)	Ratio of (B)/(A)

sentencing outcomes. The research team began by conducting a multiple regression analysis that considered the (nonracial) circumstances of each case to produce an estimate of the probability that it would result in a death sentence. They then used the results of this regression analysis to construct an eight-point egregiousness scale based on the

estimated probability that each case would result in a death sentence. Finally, the research team placed the 472 most egregious cases of the total sample into an eight-level egregiousness scale and compared the racial characteristics of actual sentencing rates within each level. The results of this regression-based analysis are provided in Table 2.

Table 2 shows that controlling for egregiousness, cases involving black defendants and white victims were substantially more likely to result in a death sentence than cases involving other combinations of defendant and victim race. Other than at the two lowest levels of the egregiousness scale (where no death sentences were imposed), a black defendant convicted of murdering a white victim was substantially more likely at each egregiousness level to be sentenced to death than either a black defendant convicted of murdering a black victim or a white defendant murdering a white victim. (As the authors noted, the racial disparities shrink at the highest egregiousness level – level 8 – since most defendants received the death penalty.)

Subsequent Studies of Race and Capital Sentencing

The Baldus team's regression models uniformly demonstrate that race infected the administration of capital punishment in Georgia during the study's sample period. Well-controlled studies using more recent data from jurisdictions across the country have similarly found that the race of the victim influences who is sentenced to die. This finding is consistent across studies and permeates both the pre- and post-1990 literature. An overview of the pre-1990 literature on the role of race in post-*Furman* capital sentencing was captured in a 1990 report of the US General Accounting Office (GAO), which issued a clear assessment of a set of studies conducted by 21 sets of researchers and based on 23 distinct datasets: "Our synthesis of the 28 studies shows a pattern of evidence indicating racial disparities in the charging, sentencing, and imposition of the death penalty after the *Furman* decision." The report also concluded:

In 82 percent of the studies, race of victim was found to influence the likelihood of being charged with capital murder or receiving the death penalty, i.e., those who murdered whites were found to be more likely to be sentenced to death than those who murdered blacks. This finding was remarkably consistent across data sets, states, data collection methods, and analytic techniques. The finding held for high, medium, and low quality studies. . . [Our] synthesis supports a strong race of victim influence.

The GAO noted that "The race of victim influence was found at all stages of the criminal justice system process, although there were variations among studies as to whether there was a race of victim influence at specific stages."

Findings that race influences the administration of capital punishment are similarly robust in the post-1990 literature. Table 3 presents the regression results of ten methodologically rigorous recent studies on the effect of victim race on capital sentencing outcomes, which have found that defendants convicted of murdering a white victim are significantly more likely to be sentenced to death than similarly situated defendants convicted of murdering a black victim (Donohue 2013). The relative probabilities presented in this table were estimated by regression models that controlled for variables that are expected to affect capital sentencing decisions.

In addition, studies that have examined the interaction between defendant and victim race have generally confirmed that black defendants are remarkably more likely to be sentenced to death if their victim is white rather than black. Table 4 displays these unadjusted rates of racial disparity. For example, in the Baldus et al. Georgia study, black defendants were 17.2 times more likely to be sentenced to death if the victim was white rather than black. The figures in this table are just overall percentages, not regression-adjusted estimates, but their uniformity is revealing.

National-Level Studies Examining Race and Capital Sentencing

In a sophisticated national-level study including 99.4% of persons admitted to death row in the United States between 1977 and 1999, researchers Blume et al. (2004) analyzed data on murders and the composition of death row from the 31 states that admitted ten or more defendants to death row during this time period. The researchers obtained data on the characteristics of murders, the racial composition of death row, and the legal and political characteristics of different states. They then compared the overall population of murderers to the death row population to determine which factors are related to the probability of being

Death Penalty, Table 3 Regression analyses on the race-of-victim effect and capital sentencing

Location	Period of study	Cases analyzed	Relative probability of being sentenced to death for killing a white victim rather than a black victim (controlling for other relevant variables)	Statistical significance
<i>Panel A: states</i>				
California	1990–1999	Reported homicides	2.46	<0.001
Georgia	1973–1979	Defendants charged with homicide and subsequently convicted of murder or voluntary manslaughter	4.3	<0.005
Florida	1976–1987	Homicides	3.42	<0.001
Illinois	1988–1997	Defendants convicted of first-degree murder	2.48	<0.01
Maryland	1978–1999	Death-eligible first- or second-degree murder cases	3.7	
Missouri	1977–1991	Nonnegligent homicides	2.61	<0.10
North Carolina	1980–2007	Homicides	2.96	<0.001
Ohio	1981–1994	Homicide	1.66	<0.01
<i>Panel B: counties</i>				
East Baton Rouge, LA	1990–2008	Defendants convicted of homicide	37.04	<0.005
Harris County, TX	1992–1999	Defendants indicted for capital murder	1.63	n/a

convicted of capital murder and placed on death row.

The researchers found that variation in black representation on states' death rows across the country can be largely predicted by three variables: (1) the overall proportion of murders committed by blacks, (2) the proportion of all murders involving a black offender and a white victim, and (3) whether a state is a former confederate state (where the large proportion of murders involve black defendants and victims). The finding that black-on-white murders were treated more harshly than other types of murders was statistically significant at the 0.01 level. Variables such as whether a judge imposes the final sentence, the amount of political pressure on judges, and state Supreme Court Justices' political ideology were not related to the proportion of blacks on death row.

Blume et al. (2004) also calculated the rate at which murder cases involving different

combinations of defendant and victim race resulted in death sentences for the eight states for which they had complete data for the period from 1977 to 2000. Table 5 displays this data and shows that cases involving a black offender and a white victim are far more likely to result in the offender being placed on death row than cases involving other combinations of offender and victim race. The combination of a black offender and a white victim leads to a death sentence roughly 3–23 times more frequently than the rate associated with black offender-black victim cases.

A New Test of Racial Bias in Capital Sentencing

In a recent working paper, Alberto F. Alesina and Eliana La Ferrara propose a novel test of racial bias in capital sentencing based on whether reversals of death sentences vary depending on the race of the defendant and victim. The authors model the behavior of the trial court as minimizing the weighted sum of the probability of sentencing an

Death Penalty, Table 4 Unadjusted rates of death sentencing in various states and counties by race of defendant/victim

Missouri	1977–1991	Nonnegligent homicides	1.2 % (24/2,033)	7.1 % (17/239)	3.3 % (3/90)	3.9 % (58/1,488)	6.03
Nebraska	1973–1999	Death-eligible homicides	8.7 % (2/23)	18.2 % (4/22)	20.0 % (1/5)	21.0 % (13/62)	2.09
Ohio	1981–1994	Homicides	2.3 % (77/3,337)	10.8 % (56/517)	4.3 % (8/184)	5.5 % (130/2,385)	4.69
Panel B: counties							
East Baton Rouge, LA	1990–2008	Defendants convicted of homicide	8.3 % (11/132)	30 % (9/30)	0 % (0/3)	12 % (3/25)	3.6

^aRaw numbers not available for Maryland

innocent defendant to death and that of letting a guilty defendant free (the inevitable trade-off between type I and type II error). The authors suggest that racial bias exists when the relative weight of these two types of errors is a function of defendant and/or victim race. Thus, if decision makers throughout the criminal justice system consider minority on white crimes to be more serious, the relative weighting of the burdens of type I and type II error might shift in favor of a greater likelihood of erroneous conviction for defendants accused of these crimes. Under the

assumption that higher courts are less likely to be affected by racial bias, one can predict that the combination of defendant and victim race will be only correlated with reversals if lower courts are affected by racial bias. The authors test this prediction by looking nationwide at all capital appeals that became final between 1973 and 1995 and by gathering information on the race of the defendant and victim(s) in these cases. They find robust evidence of bias in minority on white murders: in direct appeal and habeas corpus cases, the probability of error is 3 and 9 percentage

Arizona^a	0.5 (13/2,416)	4.8 (19/400)	2.8 (7/247)	5.9 (95/1,613)	8.8

^aNote: the data for Arizona combines blacks and Hispanics into a single “minority” category. Thus, the numbers in the last row of the table for Arizona black offender and black victim also include Hispanic offenders and victims.

points higher for minority on white murders, respectively, than for minority on minority murders.

Controlled Experiments and Social Science Evidence on the Pathways of Racially Biased Decision Making in Capital Sentencing

Some social science research has tried to illuminate the mechanisms leading to racially biased capital sentencing decisions. For example, a study by Mona Lynch and Craig Haney (2009) investigated how the process of juror deliberation can generate racially biased death penalty sentences. In their study, Lynch and Haney recruited 539 mock jurors to participate in video-simulated death penalty trials. Each juror viewed identical videos of the case, varying only the race – through both appearance and voice – of the defendant and victim. As part of their data collection, Lynch and Haney quantified “verdict certainty” by asking mock jurors to assess, both before and after deliberation, with what level of certainty they felt that the defendant deserved the death penalty for the particular homicide committed. Lynch and Haney found that after collective deliberation, not only did all jurors favor the death penalty more frequently, but the tendency to sentence black defendants to death more often than white defendants was exacerbated among white

jurors and jurors with poor instruction comprehension. Additionally, white jurors felt more certain that the nature of the homicide merited the death penalty when the defendant was black rather than white. The 2009 Lynch and Haney study also shed important light on how capital jurors evaluate mitigating and aggravating factors. Lynch and Haney found that white male jurors were less likely to consider mitigating evidence for black defendants; there was no comparable effect for women and nonwhite jurors when treated as a separate group, but the “white male dominance” of deliberation sessions nonetheless led to biased sentencing outcomes. Similarly, they conclusively found that jurors gave less weight to two categories of mitigating factors – namely, psychiatric problems and substance abuse issues – when the victim was white than when the victim was black.

Their 2009 findings accord with those of their previous study (Lynch and Haney 2000) that investigated whether juror comprehension of the judge’s instructions was a factor in sentencing bias. The authors again created a video-simulated trial that altered only the race of the victim and defendant for a “midrange” robbery-murder case. They recruited 402 jury-eligible participants to watch the videotaped trial and answer a series of questionnaires. Finally, each juror completed an

instructional comprehension test on the judicial instructions guiding their sentencing decision.

Lynch and Haney's results from 2000 revealed a bias against black defendants among those with a low comprehension of sentencing instructions. In particular, jurors who did not understand the role of mitigating and aggravating circumstances were more likely to treat mitigating factors as aggravating in black than white defendant cases. For example, when a defendant had psychiatric problems, a mitigating factor, jurors mistakenly used this as an aggravating factor for 18% of black defendants but only 9% of white defendants. Further, even when mitigation was defined properly, the evidence was regarded as "significantly less mitigating" for black than for white defendants.

Based on this finding, Lynch and Haney concluded that black defendants faced the most pronounced discrimination by those who least understood the judge's instructions, and this discrimination was manifested in a misapplication of circumstances that led to a harsher view of the crime. Haney has elsewhere identified this as the inevitable result of an "empathic divide" between white jurors and black defendants (Lynch and Haney 2009). This divide can lead jurors to engage in what Haney refers to as "moral disengagement" to separate themselves from the defendants they sentence (Haney 1997).

An important 2006 study analyzed over 600 death-eligible cases in Philadelphia, Pennsylvania, between 1979 and 1999 and showed how arbitrary this type of racial bias can be (Eberhardt et al. 2006). Forty-four of the cases involved a black defendant and white victim; another 308 had a black defendant and a black victim. Over 40 (mostly white) Stanford undergrads rated "the stereotypicality of each Black defendant's appearance" using whatever indication they felt appropriate. The study found that for cases in which Blacks Killed Whites, "24.4% of those Black defendants who fell in the lower half of the stereotypicality distribution received a death sentence, whereas 57.5% of those Black defendants who fell in the upper half received a death sentence." That this finding represents racial bias in the capital punishment regime is

underscored by the fact that when a black defendant was accused of killing a black victim, the defendant's "stereotypical blackness" did *not* predict a sentence of death. In other words, it is not something intrinsic to "stereotypical black" defendants that makes them more likely to be sentenced to death but rather how the system processes their cases when race becomes salient, as it apparently is in cases involving a black defendant who killed a white victim.

Conclusion

Despite decades of attempts to show that capital punishment deters murder, no study that purports to reach that finding has been deemed to meet the standards of modern empirical research (National Research Council 1978; Donohue and Wolfers 2005, 2009; Kovandzic et al. 2009; National Research Council 2012). Given the impossibility of employing randomized executions, it is not clear whether any stronger refutation of the deterrence hypothesis is possible.

At the same time, a large and growing literature suggests that the probability of being sentenced to death is powerfully influenced by the interaction of the race of the defendant and victim (Baldus et al. 1990; United States General Accounting Office 1990; Lynch and Haney 2000; Blume et al. 2004; Eberhardt et al. 2006; Lynch and Haney 2009; Donohue 2013). Most studies find that killers of white victims are far more likely to receive the death penalty than killers of minority victims. In addition, homicide cases with black defendants and white victims are significantly more likely to receive death penalty sentences, even when controlling for the egregiousness of the crime.

Other arenas of death penalty research in the United States have also focused on the financial cost of a death penalty system (Cook 2009; Roman et al. 2009; Alercon and Mitchell 2011) and the high rates of sentencing reversals (Liebman et al. 1999; Alesina and La Ferrara 2011), two factors that have fueled criticism of the current system. With US crime rates at a relative low after the crime surge of the late

1960s through early 1990s and with a series of DNA exonerations of death row inmates, enthusiasm for the death penalty in the United States appears to be on the decline. Whether these factors coupled with a perceived lack of deterrent benefit, the scourge of racial discrimination in implementation, and the substantial costs of a death penalty system will further the recent trends of state abolitions or be overwhelmed by a counter-insurgency by pro-death penalty forces will be one of the interesting features of the criminal justice landscape over the next decade and beyond.

Demand, Fig. 1 The demand curve (Hardes et al. 1995, p. 15)

Abstract

The term demand describes the willingness to buy a fixed quantity of goods or services at a specific price. This relation depends on the income and preferences of an individual but is typically expressed as an overall economic aggregate. The disposition to buy normally alters in contrary to the price.

Introduction

Demand represents the relation between demanded, purchased quantity of a good and the market price. Generally it is to express that with an increasing price of good, the willingness to buy is declining and also in the opposite way, that with a decreasing price of good, the willingness to buy a good is increasing. This relation is called the law of downward-sloping demand and can be described also through a graph in the form of a demand curve. The quantity of a good is on the horizontal axis and the price on the vertical axis, so the quantity and price are inversely related. That means the dependent volume is quantity and the independent volume the price (Samuelson and Nordhaus 1992). The demand curve slopes downward (Fig. 1):

The first, who graphically defined the demand, was in the nineteenth century A. Marshall.

When describing and analyzing the demand, it is important to distinguish the type of demanded good, that's why we are speaking about the demand for consumer goods and the demand for production factors.

Demand for Consumer Goods

Demand for consumer goods is affected besides the price also by several non-price factors, which effect we can express, if we consider the price as a fixed value (compliance with the condition of *ceteris paribus*). Factors other than price influencing demand are price change of substitute goods, price change of complementary goods, change in the number of households on the market, change of the buyer's income, change of consumer's preferences, expectation of a future good's price change, or exceptional circumstances.

The substitute good is a good which replaces the original good and which satisfies the same need, for example, glasses and contact lenses or ice cream and ice lolly. If there is a price change of a substitute good, it affects the original good's demand, for example, if the price of a substitute good (price of an ice cream) decreases, then the demand for the original good (ice lolly) drops without a change in the price of the original good (ice lolly) (Fig. 2).

Complementary goods represent goods, in which consumption is interlinked or supplemented, for example, computer and software or skis and sky shoes. In this kind of goods, it is also applied that if the price of a complementary good changes, it affects also the original good's demand. For example, if the price of software of several companies increases, not only the demand for the software decreases due to the effects of the law of decreasing demand but also the demand for computers. Thus price increases of a complementary good will cause a

Demand, Fig. 2 Price change of a substitute good as a factor influencing demand (own; Samuelson and Nordhaus 1992, p. 59; Frank and Bernanke 2011/2009, p. 75)

decrease of demand for a complementary good and also for an original good. If the price of a complementary good decreases, the demand for complementary good will increase and also the demand for an original good will increase.

A change of the number of households can affect the demand in a following way. Should the number of buyers increase, for example, due to migration, then the demand at such a market will increase and the demand curve moves to the right. Other way round, should the number of buyers decrease, there will be less subjects who will buy and that's why also the total demand at the market will decrease and the whole demand curve moves to the left.

A change in the income of consumers is also an important factor affecting the demand at the market. When the income of consumers is increasing, their willingness to buy is also increasing and that's why the demand is increasing and the demand curve moves to the right. If the income of consumers is decreasing, this factor affects in the opposite way.

Change in preferences of consumers is a reaction of the consumers, for example, to fashion trends (tight jeans) or to the change of lifestyle (preference of a healthy lifestyle); they are related also to hobbies or as a reaction on seller's marketing tools. If any impulse causes a growth in preferences of specific products, there is also an increase of demand and the demand curve of such products moves to the right.

Consumers can have future expectations that the price of a good will increase or decrease. If they expect that the future price will be lower, for

example, sellouts and after-Christmas discounts, today they will demand less and the demand curve moves to the left. If they expect that the future price will grow, today they will demand more and buy on stock and the demand curve moves to the right.

Demand is affected also by many exceptional factors and unexpected circumstances, for example, epidemics and floods, which increase the demand for concrete goods.

Distinguishing Between the Movement on the Curve and the Movement of the Curve

Considering demand one has to distinguish between a shift of demand and a change along the demand curve. For example, demand shifts if the preferences of individuals vary or if the future expectations change. In contrary to that, a change in the price induces movements along the demand curve without shifting it.

Income and Substitute Effect

The existence of the law of decreasing demand is connected with and explained by two reasons (effects): the income and substitute effect. If the price of a good is increasing, then the substitute effect expresses the consumer's effort to replace – substitute the consumption of an original good, in which price has increased, with a substitute good. When increasing price of a good, also

the income effect appears. It describes the behavior of consumers, so the consumers are feeling poorer when the price of goods is increasing. Thus the consumers will buy and demand less of a good, which has become more expensive (Frank and Bernanke 2011/2009, p. 65)

Giffen's Goods and the Demand of Inferior and Luxury Goods

The already described law of decreasing demand applies in a large extent, but it does not apply absolutely. However, it is possible that an increase in price level leads to an increase in demand, so-called Giffen paradox. It was found first by R. Giffen, who observed the demand for bread and meat of poor people in Ireland (Marshall 1997). In his considerations bread was an inferior product. This means that a higher income leads to lower demand for bread and higher demand for meat. He discovered that an increase in the bread price lead to an increase in the demand for bread. A modern approach to discuss Giffen's goods is delivered by Jensen and Miller (2008).

Demand Elasticity

Although the law of decreasing demand suggests that with the growth of price, the market demand will decrease, such a statement is not clear about how much the demand will decrease. This is answered by the direct price elasticity, which expresses what the percentage change of demanded goods will be, if the price of a good changes. Direct price elasticity is measured by the elasticity coefficient, which can be in the interval $<0, \infty>$ (Siebert 1996, pp. 79–82). The higher the number of the coefficient, the bigger is the reaction of demand to the price change and thus the bigger is the elasticity of demand. The more the demand is elastic, the more the demand curve is horizontal and vice versa; the less elasticity, the more vertical the demand curve. Besides the direct price demand elasticity, also income demand elasticity and indirect price demand elasticity exist.

Individual, Market, and Aggregate Demand

If we are analyzing one consumer's demand and how this consumer chooses demanded quantities related to different prices, such a demand is referred to as an individual demand. It expresses the relation between different prices of the good and of quantity what one consumer would demand related to the price. His demand is expressed by the individual demand curve, and it can be derived through an indifference analysis when examining the consumer's optimum through indifference curves and budget lines.

The sum of individual demands will create a market demand, which is the demand of all consumers for one good. Aggregate demand is a demand of all subjects for all goods in the economy.

Production Factor's Demand

Demand for consumer goods determines how the demand for production factors will be; that's why we are saying that the demand for production factors is a derived demand.

Conclusion

Demand analysis is always connected to concrete goods or to a concrete group of consumers or to concrete markets. If we want to better understand the functioning of markets through the demand analysis, it is appropriate to link the demand analysis with supply.

Abstract

This chapter argues that economic development originates not from the gains from trade and specialization under a division of labor but fundamentally from an institutional framework of property rights which permits the gains from trade and innovation that emerge on a societal wide scale. It is this framework that enables the transition from small-scale trading and capital accumulation to medium-scale trading and capital accumulation and finally to large-scale trading and capital accumulation. All of humanity was once poor; those societies that have been able to escape from poverty are those that were able to get on this development path by adopting the institutional framework of property, contract, and consent. We argue that well-defined and exchangeable private property rights yield economic growth by operating as a filter on economic behavior – the establishment of property rights embedded in the rule of law weeds out unproductive entrepreneurship and the corresponding politicized redistribution of property rights, with rent-

seeking and predation as its consequence, and engenders instead productive entrepreneurship and a more efficient allocation of property rights and with that a realization of the gains from trade and the gains from innovation. The fundamental cause of economic development, we argue, is the institution of private property, as it is this institutional framework that results in productive specialization and peaceful cooperation among diverse and disparate individuals.

Introduction

In the introduction to their book, *How the West Grew Rich*, Rosenberg and Birdzell (1986) argue that little controversy exists that institutions, namely, private property rights as well as the rule of law and enforcement of contracts, are the fundamental determinant to economic growth. There is a general consensus among economists that the unprecedented gains in labor productivity and innovation beginning in the nineteenth-century England cannot be attributed exclusively to the proximate causes of growth, such as the expansion of international trade, the accumulation of physical capital, or utilization of the economies of scale, all of which by themselves exhibit diminishing returns to scale (Phelps 2013, pp. 5–8; McCloskey 2010, pp. 133–177). Rather, the fundamental cause of modern economic growth is the institutional framework that makes possible the increasing specialization and widening circle of exchange. The “virtuous cycle” is implied in Adam Smith’s famous dictum that the “division of labor is limited by the extent of the market.” Increased possibilities of trade result in increasing specialization and a more extensive division of labor, which in turn increases the productive capacity of individuals and leads to great trading opportunities. With specialization and trade, there is also great scope of opportunities for innovation.

An understanding of how private property generates economic development also provides a perspective of the processes that emerge from such an institutional environment, which is necessary for prosperity. Observation of countries around the

world indicates that those countries with an institutional environment of secure property rights have achieved higher levels of various measures of human well being, including not only higher GDP per capita, but also lower infant mortality rates and higher rates of education. Private property rights structure human interaction by providing individuals three main mechanisms of social coordination and conflict resolution: (1) excludability, (2) accountability, and (3) exchangeability.

Well-defined and exchangeable private property rights yield economic growth by operating as an entrepreneurial filter. By structuring the costs and benefits of exchange, private property rights economize on the emergence of certain patterns of behavior by (1) filtering in productive entrepreneurship, leading to a more efficient partitioning of property rights and technological innovation as its outcome, and (2) filtering out unproductive entrepreneurship that leads to a politicized redistribution of property rights with rent-seeking and predation as its consequence.

The basic thesis of this entry is that the process of economic development goes as follows: the only way to achieve sustained increases in real income is to increase real productivity. Such increases in real productivity come from investments and technological innovation that increase and improve physical and human capital. However, because of the heterogeneity of capital, capital accumulation is a necessary, though not a sufficient, condition for economic growth. Such capital formation can only be undertaken through a decentralized price system, which coordinates the particularized insights of entrepreneurs about opportunities for gains from trade and gains from innovation. This manifests itself in technological change by discovering new and improved combinations of land, labor, and capital to satisfy the most valued consumer demands. The production plans of some must mesh with the consumption demands of others, and this is accomplished through the guiding influence of monetary calculation and the weighing of alternative investment decisions. Moreover, the allocation of entrepreneurship into productive activities that improve productivity and increase real income depends upon an institutional framework that widens the

extent of the market for entrepreneurs “where they can take advantage of increasing returns to ability” (Murphy et al. 1991, p. 510). An institutional framework of secure and exchangeable private property rights is sufficient for the emergence of a decentralized price system that provides profit and loss signals to entrepreneurs to discover new technological opportunities, generating economic growth.

We Were All Once Poor

Since at least the days of Adam Smith, economists have debated why certain societies have grown rich while others have remained stagnant and poor. Despite the unprecedented economic growth that has transformed the West and more recently China and India, many parts of the world today, particularly sub-Saharan Africa, are still poverty stricken. Many development economists, most notably Jeffrey Sachs, have argued that sub-Saharan Africa has been stuck in a “poverty trap,” resulting in unsustainable levels of economic growth that are not robust enough to bring Africa out of poverty. Africa’s extreme poverty levels lead to low savings rates, which in turn lead to low or negative economic growth, which cannot be offset by large inflows of foreign capital. Therefore, an investment strategy focusing on specific *interventions*, defined broadly as the provision of goods, services, and infrastructure, would be required, including improved education, which in turn leads to reductions in income poverty, hunger, and child mortality. The concept of a “poverty trap” has been a long-standing hypothesis in theories of economic growth and development (Sachs et al. 2004).

The underlying premise behind the poverty trap hypothesis is that the conditions of poverty are unique to Africa and other developing regions around the world and that the West has been uniquely endowed with economic wealth. The poverty trap hypothesis leads to the presumption that the West can save Africa (Easterly 2009), particularly through increasing transfers of foreign aid. However, development economist Peter Bauer, one of the most outspoken critics of

modern development economics in the twentieth century, wrote the following:

To have money is the result of economic achievement, not its precondition. That this is so is plain from the very existence of developed countries, all of which originally must have been underdeveloped and yet progressed without external donations. The world was not created in two parts, one with ready-made infrastructure and stock of capital, and the other without such facilities. Moreover, many poor countries progressed rapidly in the hundred years or so before the emergence of modern development economics and the canvassing of the vicious circle. Indeed, if the notion of the vicious circle of poverty were valid, mankind would still be living in the Old Stone Age. (2000, p. 6)

The engine of growth that transforms a society from “subsistence to exchange” (Bauer 2000, p. 3) is trading activity, leading to what Adam Smith recognized as “the greatest improvement in the productive powers of labour, and the greater part of the skill, dexterity, and judgment with which is any where directed, or applied, seemed to have been the effects of the division of labour” (Smith 1776[1981], p. 13). The absence of exchange opportunities precludes social cooperation under the division of labor and the emergence of specialized skills and crafts.

Smith pointed out that the division of labor was limited by the extent of the market. By widening its extent, individuals could capture increasing returns from specialization and trade. While Smith had emphasized the role of international trade in promoting economic growth, Bauer focused on the neglect among development economists of “internal trading activity” which in emerging economies leads to “not only the more efficient deployment of available resources, but also the growth of resources” (2000, p. 4). When individuals exercise their comparative advantage, not only are they able to produce goods and services beyond their subsistence level of consumption, but such surplus consumption can be deferred as savings and investment, not only in physical capital but also in human capital. Through increasing investments in physical and human capital, economies become more productive.

What is lost among First World observers is that in the developing world, much of this investment takes place in nonmonetary forms. As most

production in the developing countries is labor intensive and agriculturally based, “these investments include the clearing and improvement of land and the acquisition of livestock and equipment. Such investments constitute capital formation” (Bauer 2000, p. 11). Because much of this investment is not calculated in money prices, these forms of investment “are generally omitted from official statistics and are still largely ignored in both the academic and the official development literature” (Bauer 2000, p. 11).

The fundamental basis of economic development from subsistence to exchange entails well-defined, enforceable, and exchangeable property rights. Most of the developing world today remains poor because governments are predatory or because governments are unable to enforce private property rights, precluding the advance from subsistence to exchange. Just as Bauer pointed out that the “small-scale operations” of trade and nonmonetary investment are required for economic development, analytically speaking, what allowed for the birth of economic development in the West and in those emerging economies embarking in economic growth today was the development of various types of property rights arrangements:

We ought not to be surprised if we find that in the relatively short history of man, he has already devised, tested, and retained an enormous variety of allocations and sharing of property rights. The history of the law of property reveals an overwhelming and literally incomprehensible variety. (Alchian 1961[2006], p. 33)

The absence of tried and tested mechanisms of private property rights and their enforcement would have thwarted modern economic growth in the West and those developing countries emerging from poverty today. Within the framework of private property rights under the rule of law, individuals are able to form reliable expectations about how their land, labor, capital, and entrepreneurial talent can be permissibly utilized. In rich countries, property rights provide a framework of rules that provide a degree of legal certainty so that individuals reliably coordinate their actions amid the flux and “throng of economic possibilities that one can only dimly perceive” (Mises

1922[2008], p. 117) over an uncertain economic horizon.

Some Development Economics of Property Rights

James Buchanan stated “the economist should not be content with postulating models and then working within such models. His task includes the derivation of the institutional order itself from the set of elementary behavioral hypotheses with which he commences. In this manner, genuine institutional economic becomes a significant and important part of fundamental economic theory” (Buchanan 1968[1999], p. 5). However, throughout most of the twentieth century, neoclassical economists have largely neglected the framework within which exchange and production takes place. In the textbook neoclassical model, individuals are presumed to have perfect information and are able to engage in costless exchange without incurring any externalities, or third-party effects, on other individuals. Property rights are the given background of analysis of competitively perfect markets, but a theoretical framework cannot account for the innumerable contractual arrangements, such as firms and money, that emerge in order to reduce the transaction costs of engaging in market exchange.

However, the economic analysis of property rights, although neglected, was not completely overlooked. Scholars working within the property rights, law and economics, public choice, and Austrian market process perspectives all took property rights out from underneath the cover of the “given background” to analyze the evolution and allocation of property rights and how alternative institutional arrangements of property rights will have different consequences on the pattern of exchange and production. The leading twentieth-century economists who emphasized the importance of private property rights to economic theory were Ludwig von Mises, Friedrich Hayek, James Buchanan, Ronald Coase, Armen Alchian, and Harold Demsetz. Their research emphasized how different delineations of property rights lead to different economic outcomes. Because of

scarcity of knowledge and other resources, competition among individuals emerges in all societies. However, the manner in which competition manifests itself was *institutionally contingent* to the cost-benefit structure of property rights. But as neoclassical economics grew increasingly focused on static equilibrium analysis after the 1930s, what emerged was an institutionally anti-septic theory of choice. This preoccupation with the properties of static equilibrium shifted theoretical attention away from the institutional context of choice, namely, how private property rights structure the marginal costs and benefits of choice that generate a dynamic tendency toward equilibrium (Boettke 1994[2001], p. 236). Economist Svetozar Pejovich defines property rights in this way:

Property rights are relations among individuals that arise from the existence of scarce goods and pertain to their use. They are the norms of behavior that individuals must observe in interaction with others or bear the costs of violation. Property rights do not define the relationship between individuals and objects. Instead, they define the relationship among individuals with respect to all scarce goods. The prevailing institutions are the aggregation of property rights that individuals have. (italics original, 1998, p. 57)

Private property rights structure human interaction by providing individuals three main mechanisms of social coordination and conflict resolution: (1) excludability, (2) accountability, and (3) exchangeability. Excludability means that individuals are free to use and dispose of their property rights over a particular resource and exclude other individuals from utilizing their property rights so long as they do not violate the property rights of other individuals, namely, the physical properties of their body and the resources they own.

Accountability assigns residual claimancy over the costs and benefits of an action initiated by an individual. Without private ownership, when a person uses resources, they impose a cost on everyone else in the society, leading to a tragedy of the commons. Therefore, private property rights provide accountability over the costs and benefits of individual's actions through the internalization of positive and negative

externalities (Demsetz 1967, p. 350). Through such internalization, private property rights over resources provide the incentive for individuals to maximize the present value of their resources by taking into account alternative future time streams of benefits and costs and selecting that one which he believes will maximize the present value of his resources. Private property incentivizes individuals to economize on resource use and maintain capital for future production because the user bears the costs of their actions. Poorly defined and enforced property rights lead to overuse and depletion of resources since the decision maker of a particular action does not bear the full cost of his action.

Exchangeability of property rights not only allows individuals to make trades that both parties believe will make them better off. When rights over private property are transferable, it also provides an institutional framework within which a system of money prices emerges. The emergence of money prices provides the information to calculate the relative scarcity of different resources, such that “prices can act to coordinate the separate actions of different people” by communicating the dispersed and particular knowledge of millions of individuals (Hayek 1945, p. 526). People are able to observe prices and determine whether they value the property they have more than the money they could receive for it. Changes in price signals drive the movements in the demand and supply for different goods and services. These price changes provide the information to entrepreneurs as to what products are most urgently demanded and what inputs can be combined to most cheaply produce them. Absent the free exchange of private property rights, this *contextual* information embodied in money prices is not generated (Mises 1920[1975]). Since entrepreneurs have a property right, or residual claimancy, over their profits and losses, they also have every incentive to use resources to satisfy these most highly valued demands.

The crucial link between private property rights and such unprecedented economic growth lies with increasing returns to the division of knowledge embodied in entrepreneurial activity. As the extent and complexity of the market widen,

so do the complexity and specialization of knowledge within the market. The effective partitioning of property rights enables individuals to specialize in applying their particularized knowledge of time and circumstance in the discovery of previously unnoticed profit opportunities conducive to capital investment and technological progress (Alchian 1965[2006], p. 63). Through this process, entrepreneurship effectively leads to greater productivity, higher real wages, an expansion of output, and an overall increase in human welfare.

Property Rights and Entrepreneurship

Certain institutional frameworks encourage the spontaneous order of the market economy, as well as its entrepreneurial drive towards economic growth, while others erect barriers to growth and pervert the incentives of entrepreneurs towards rent-seeking and predation. Private property rights and their exchangeability ensure the emergence of a spontaneous order, in which entrepreneurs are driven by consumer preferences and encouraged to invest in enterprises that spur innovation and create wealth. Through purposeful actions of entrepreneurs, economic resources and knowledge, which are dispersed and particular to time and place, are coordinated through the incentives of the price system. However, how entrepreneurs coordinate economic knowledge and resources depends heavily on the institutional framework, or the rules of the game, that happen to prevail in the economy.

The prosperity or stagnation of societies rests on the allocation of entrepreneurship (Baumol 1990). The institutions that constrain human behavior within a particular society largely influence how entrepreneurial activity will be allocated and the nature of their purpose, which may be productive or unproductive in result. In prosperous societies, in which exchangeable private property rights have prevailed, entrepreneurship has been driven by consumer preferences and led the market process to more efficient outcomes, leading to economic growth. Poor and stagnating societies are characterized by institutions that are interventionist and arbitrary, leading to the

politicization of entrepreneurial activity. Such an environment encourages rent-seeking and predation and discourages innovation, capital investment, and economic growth.

It is not only because individuals have limited means to satisfy their innumerable wants that property rights structure the rewards and costs of human interaction but more fundamentally because knowledge about how to *discover* such means is scarce as well. Property rights structure the costs and rewards of utilizing particularized knowledge in the application and specialization of particular forms of entrepreneurial talent, both productive and unproductive.

Moreover, private property rights yield economic growth by operating as an entrepreneurial filter. By structuring the costs and benefits of exchange, private property rights economize on the emergence of certain patterns of behavior by filtering in productive entrepreneurship, leading to technological innovation and enhanced productivity, and filtering out unproductive entrepreneurship, which leads to rent-seeking and predation. In a world of uncertainty, the means by which individuals pursue different economic ends are unknown and must be discovered through entrepreneurship.

According to Israel Kirzner (1988, p. 179), entrepreneurship refers to the process of individuals acting upon profit opportunities “that could, in principle, have been costlessly grasped earlier.” In *Competition and Entrepreneurship*, Kirzner further elaborates on the process of entrepreneurship:

The entrepreneur is someone who hires the factors of production. Among these factors may be persons with superior knowledge of market information, but the very fact that these hired possessors of information have not *themselves* exploited it shows that, in perhaps the truest sense, their knowledge is possessed not by them, but by the one who is hiring them. It is the latter who “knows” whom to hire, who “knows” where to find those with the market information needed to locate profit opportunities. Without himself possessing the facts known to those he hires, the hiring entrepreneur does nonetheless “know” these facts, in the sense that his alertness – his propensity to know where to look for information – dominates the course of events. (Kirzner 1973, p. 68, *italics original*)

Kirzner also states “the discovery of a profit opportunity *means the discovery of something obtainable for nothing at all*. No investment at all is required; the free ten-dollar bill is discovered to be already within one’s grasp” (Kirzner 1973, p. 48, *emphasis in original*). The entrepreneur’s role in the production process is to earn pure profit based on his “alertness” of where to find market data under uncertainty (Kirzner 1973, p. 67). It entails that the entrepreneur possesses the right knowledge at the right time for discovering new combinations of technological inputs for the production of new goods and services to their most valued uses. The entrepreneur does not mechanically respond to profit opportunities as a calculative, maximizing *homo economicus*. Rather, he is “alert” to price discrepancies between existing commodities and to discovering previously unknown opportunities for mutually beneficial exchange. It is the entrepreneurial element in each individual “that is responsible for our understanding of human action as active, creative, and human rather than as passive, automatic, and mechanical” (Kirzner 1973, p. 35). It is through the discovery of profit opportunities that entrepreneurs discover how resources must be allocated to satisfy their most valued uses.

The Smithian growth process that was described above rests not only on passive capital accumulation but more importantly on the increasing returns to knowledge that enlarge the extent for entrepreneurial activity. The emergence of knowledge externalities through the entrepreneurial pursuit of pure profit opportunities links the fundamental relationship between private property rights and economic growth (Holcombe 1998, pp. 51–52). Demsetz states that:

Property rights develop to internalize externalities when the gains of internalization become larger than the cost of internalization. Increased internalization, in the main, results from changes in economic values, changes which stem from the development of new technology and the opening of new markets, changes to which old property rights are poorly attuned. (1967, p. 350)

Following Kirzner, Holcombe goes further to state that entrepreneurship drives the changes in relative prices and technology, from which:

Knowledge externalities occur when the entrepreneurial insights of some produce entrepreneurial opportunities for others. Increasing returns occur because the more entrepreneurial activity an economy exhibits, the more new entrepreneurial opportunities it creates. (Holcombe 1998, p. 58)

The key to understanding the engine that drives the market economy towards efficient outcomes is the fact that today's inefficiencies are tomorrow's profit opportunities for entrepreneurs to seize upon such externalities of knowledge. However, this entrepreneurial market process requires that private property rights assign to entrepreneurs residual claimancy over the costs and rewards of their actions in the form of monetary profits and loss. The consequence of poorly defined property rights will be the destruction of wealth. Without secure property rights, economic calculation will break down, as money prices will not reflect the relative economic profitability of using different quantities and qualities of scarce inputs, such as land, labor, and capital. As a result, insecure property rights will shrink the extent of the market for productive entrepreneurship. Murphy et al. (1991) also point out that unproductive entrepreneurship is more prevalent in countries with poorly defined property rights since the market for rent-seeking is larger and more lucrative there. As they argue, "rent seeking pays because a lot of wealth is up for grabs," (1991, p. 519) particularly for those entrepreneurs who are successful at defining property rights through bribery, theft, or litigation. Such entrepreneurial activity is wasteful since entrepreneurs are committing their time, knowledge, and resources not to creating more efficient ways of producing goods and services but in transferring wealth or resisting other entrepreneurial competitors from capturing their rents (Tullock 1967, p. 228).

Conclusion

Economic development originates from trading activity, specialization, and social cooperation under a division of labor. But the *cause* of economic development is inextricably linked with a framework of well-defined, enforceable, and exchangeable private property rights. Economic

growth and development, driven by entrepreneurship, cannot be explained independent of its institutional context, namely, private property rights. Entrepreneurship by itself cannot be the fundamental cause of economic development, since scarcity, competition, and entrepreneurship exist in all societies. Rather, the manner in which entrepreneurship manifests itself is a *consequence* of the structure of property rights (Boettke and Coyne 2003). The fundamental cause of economic development is the adoption of well-defined and exchangeable private property rights, which incentivizes entrepreneurship to act on profit opportunities that facilitate increasing gains from exchange and specialization, spurring capital investment, increased labor productivity, and higher real income.

Recognizing the link between property rights, entrepreneurship, and economic growth has important implications not only for economic theory but also for economic policy as well. Assuming away the institutional differences in property rights arrangements across countries leads to misleading policy advice about how poor nations can emerge from poverty. In the wake of the fall of the Berlin Wall and the collapse of communism in Eastern Europe, Peter Murrell asked whether neo-classical economics could underpin the reform of centrally planned economies. As he wrote, "reformers need a filter that interprets the experience of capitalist and socialist systems" (Murrell 1991, p. 59). Such a filter refers to a comparative institutional analysis of property rights that have emerged to fit the historical and cultural context of a particular time and place.

By focusing on the accumulation of production inputs, such as physical and human capital, to increase productivity and real income, economic policymakers have focused on investment as well as research and development to spur economic growth. However, failing to take account of the framework of property rights misleadingly places factor accumulation as a fundamental cause of economic development, rather than as a proximate cause. Capital investment by itself does not cause economic growth but emerges in response to productive entrepreneurship incentivized by a framework of private property.

Abstract

The difference-in-difference (DiD) is one of the most popular approaches to evaluate causal effects of programs or policies. The idea is very simple: a treatment group is affected by an external change in one period, and the main aim is to evaluate how this treated group changes after the policy, regarding a control group that is not affected. So it controls the double difference (changes over time and over control group). Although some assumptions have to be assumed, its flexibility and requiring a relatively small volume of data yield to a large number of papers and documents that use it on topics as competition policy, merger evaluations, political economy, and so on.

The difference-in-difference (DiD) is one of the most popular approaches to evaluate causal effects of programs or policies. This empirical strategy has become widespread not only in economics but also in other social sciences. Although it shows some assumptions and it is not without criticism, a lot of academic research and private and public documents use this technique.

The idea is very simple: We have data on two similar groups of interest in two different periods. One of them is affected by an external policy in the second period (the treated group). The main aim is to evaluate how the treated group changes after the policy, regarding the other, i.e., the control group. The DiD not only considers differences by group but by time. In fact, as Imbens and Wooldridge (2009) state, in this double difference, the average gain over time in the control group is subtracted from the gain over time in the treated group.

The Structure of a Difference-In-Difference Analysis

The setting of this model can be summarized as follows. We have two groups (treated and control) in two different periods (1 or before and 2 or after). In period 2, a treatment occurs and affects only to the treated group. Our aim is to evaluate how the outcome (prices, quantities, wages, GDP, or any variable of interest) changes due to the treatment. So we have to consider both the time effect that incides in two groups and the previous differences by group.

Table 1 includes the outcome in each situation (subscript 0 is before; Superscript TRT is Treated group and CRT is Control group). On one hand, if we calculate the differences between after and before by groups, we are not considering differences by group (last column). On the other hand,

if we only consider the difference between treated and control group, we are not considering time effects (last row). For these reasons, the cornerstone is to evaluate these two differences simultaneously, i.e., how treated changes regarding how control changes (last cell in Table 1).

Equation (1) shows the basic model to estimate in a pool database:

$$\begin{aligned} \text{Endogenous}_{it} = & \beta_0 + \beta_1 \text{After}_t + \beta_2 \text{Treated}_i \\ & + \beta_3 \text{After} * \text{Treated} (\text{Interaction})_{it} \\ & + \sum_{j=4}^n \beta_j X_{it} + \varepsilon_{it} \end{aligned} \quad (1)$$

Estimations simultaneously have to include three binary variables: after, treated, and the interaction of these two covariates (the coefficient β_3). The former takes value 1 for two groups in the period 2. The variable treated takes value 1 if the observation corresponds to the treated group, regardless the period. The latter attempts to assess the causal effect of the treatment in the treated group.

Empirically, this effect is summarized in Table 2.

Assumptions and Robustness Checks

One of the pillars of the difference-in-difference is that the policy or change analyzed was an

Difference-in-Difference, Table 1 Explanation of coefficients for Eq. (1) and subsequents

		Time effect		Difference (Af–Be)
		Before (Be)	After (Af)	
Group effect	Control (Co)	Y_0^{TRT}	Y_1^{TRT}	$Y_1^{\text{TRT}} - Y_0^{\text{TRT}}$
	Treated (Tr)	Y_0^{CRT}	Y_1^{CRT}	$Y_1^{\text{CRT}} - Y_0^{\text{CRT}}$
Difference (Tr–Co)		$Y_0^{\text{TRT}} - Y_0^{\text{CRT}}$	$Y_1^{\text{TRT}} - Y_1^{\text{CRT}}$	$Y_1^{\text{TRT}} - Y_1^{\text{CRT}} - (Y_0^{\text{TRT}} - Y_0^{\text{CRT}})$

Difference-in-Difference, Table 2 Explanation of coefficients for Eq. (1)

		Time effect		Difference (Af–Be)
		Before (Be)	After (Af)	
Group effect	Control (Co)	β_0	$\beta_0 + \beta_1$	β_1
	Treated (Tr)	$\beta_0 + \beta_2$	$\beta_0 + \beta_1 + \beta_2 + \beta_3$	$\beta_1 + \beta_3$
Difference (Tr–Co)		β_2	$\beta_2 + \beta_3$	β_3

exogenous change, as Lafontaine and Slade (2008) point out. It has been called as a “natural experiment,” which refers to an analysis that fulfills these three conditions (exogenous change, a group affected by the change, and an unaffected group).

Another of the main basic assumptions of the difference-in-difference models is that the temporal effect in the two groups is the same in the absence of the exogenous change. This has been called the “identifying assumption.” So, we first have to test whether both treatment and control group show the same trend before the change. In order to check it, we estimate a similar equation than Eq. (1) but we substitute DiD estimator by separate dummies for treatment and control groups, in order to check whether the time trends in the pretreatment period were the same.

The empirical strategy is the following one: firstly we create time dummies for both control and treatment group. Then, we estimate each equation replacing DiD variables for these previous variables generated. Finally, we test whether coefficients for each group of time dummies are equal or not (see Albalade 2008, for further explanation of this empirical strategy).

Simplicity aside, its great advantage is its potential to avoid many of the problems of endogeneity that habitually arise when carrying out comparisons among heterogeneous individuals (see Bertrand et al. 2004). Nevertheless, these authors also argue that DiD is in practice subject to a possibly serial correlation problem.

A second possible criticism is the potential endogeneity in the change in the market. When the change that occurs in the market is not exogenous, the DiD estimator will be biased and inconsistent. For example, it is clear that the decisions of merger between two or more firms are not exogenous and depend on their pricing decisions. The endogeneity problem is explained and discussed in-depth by Dafny (2009).

Some robustness checks are usually implemented in this empirical strategy. These placebo tests affect both date of treatment, treated group, and/or endogenous variable. Regarding the former, new estimations can be made changing the date of the treatment. If the DiD variable

shows the same result as in the original estimations, some problem arises.

The second placebo test can be to replace the treated group for some control groups (and vice versa). As in the previous test, we expect empirical changes in the outcome. Finally, new endogenous variables must be considered in order to control for general effects on all variables after treatment regarding the control group.

Where Has DiD Been Applied? Some Empirical Findings

The DiD estimator is extremely flexible and requires a relatively small volume of data, so it has been applied increasingly in the empirical analysis of many different aspects. It is impossible to summarize the whole set of empirical applications that have used this empirical approach, so we will only indicate some of the main aspects related to the competition policy analyzed through this indicator.

A first element is the analysis of the effects produced by the horizontal mergers. Although the authorization or not of the horizontal mergers requires an ex ante analysis, which it is impossible to realize through a methodology like the DiD, this empirical approximation can be very useful to observe the real effects that have been, and if the ex ante analysis was, accurate or not. In this sense, Peters (2006) pointed out that the simulations performed ex ante underestimated the potential effects of the mergers, as showed the results of the DiD estimator in the ex post analysis.

Equally, Hosken et al. (2017) expose the benefits of using ex post merger evaluation for ex ante analysis. Concretely they expose that ex post merger evaluations can be used to evaluate the accuracy of merger simulations by comparing predictions versus evaluations. European Commission (ex post analysis of two mobile telecom mergers: T-Mobile/tele.ring in Austria and T-Mobile/Orange in the Netherlands) and Austrian Competition Authority (BWB 2016, The Austrian market for mobile telecommunication services to private customers – An ex-post evaluation of the mergers H3G/Orange and TA/Yees!) provided two examples of it. Both documents use a difference-in-difference analysis to measure the effect of the evaluated merger.

There is a large number of examples that analyze the effects of horizontal mergers, obtained through the DiD estimator, in different sectors: in the air sector (Kim and Singal 1993; Peters 2006; Dobson and Piga 2013; or Fageda and Perdigueró 2014), in the petrol market (Taylor and Hosken 2007; Simpson and Taylor 2008; or Jiménez and Perdigueró *forthcoming*), in the scientific journals market (McCabe 2002), in the banking sector (Prager and Hannan 1998; Focarelli and Panetta 2003), or in the health sector (Connor et al. 1998; Vita and Sacher 2001; Dafny 2009). A good example of their versatility among different sectors is the paper by Ashenfelter and Hosken (2010), which analyzes the effect on prices in five different industries (female hygiene products, alcoholic drinks, lubricating oil, cereals, and breakfast syrups).

Although DiD has been used to a greater extent in the analysis of the ex post effects of horizontal mergers, it has also been used for the analysis of other equally important issues in competition policy, such as entry (Bernardo 2016), although respecting the DiD assumption of randomness in group formation is difficult, or restricting vertical relations (Vita 2000).

Outside the field of competition policy, DiD is increasingly being used to measure the impact of a broad range of public policies. Some examples are the impact of water service privatization on infant mortality (Galiani et al. 2005), the effect of the reduction of maximum permitted levels of alcohol and number of traffic accidents (Albalade 2008), the effects of the “Cash for Clunkers” programs (Jiménez et al. 2016), the effects of certain infrastructures on tourism (Albalade and Fageda 2016), the alignment of parties and the intergovernmental transfers (Solé-Ollé and Sorribas-Navarro 2008), or the effects of corruption on voters (Costas-Pérez et al. 2012) or on municipal budgets (Artés et al. 2016).

Digital Piracy

Paul Belleflamme¹ and Martin Peitz²

¹CORE and LSM, Université catholique de Louvain, Louvain-la-Neuve, Belgium

²Department of Economics, University of Mannheim, Mannheim, Germany

Definition

Digital piracy is the act of reproducing, using, or distributing information products, in digital formats and/or using digital technologies, without the authorization of their legal owners.

Introduction

The objective of this entry is to provide a comprehensive and up-to-date overview of digital piracy (this entry summarizes and updates Belleflamme and Peitz (2012)). Although we put the emphasis on the economic analysis, we also briefly present the legal context and its recent

evolution. As digital piracy consists in infringing intellectual property laws, it is important to start by understanding the rationale of such laws. That allows us to define more precisely what is meant by digital piracy. We can then move to the economic analysis of piracy. We start with the basic analysis, which explains why piracy is likely to decrease the profits of the producers of digital products; we also examine how the producers have reacted to digital piracy when it started to grow. We review next more recent contributions that point at possible channels through which piracy could improve the profitability of digital products. These channels have inspired new business models for the distribution of digital products, which we describe in the last part of the entry. Throughout the entry, we report the results of some of the most recent empirical studies, so as to quantify the impacts of digital piracy.

The Intellectual Property (IP) Protection of Information Products

Information products (such as music, movies, books, and software) are often characterized as being hardly excludable, in the sense that their creators face a hard time excluding other persons, especially non-payers, from consuming these products. This feature may undermine the incentives to create, because of the difficulty in appropriating the revenues of the creation. The production of information products may then be insufficient compared to what society would deem as optimal. One solution to this so-called “underproduction” problem is to make intellectual creations excludable by legal means. This is the objective pursued by intellectual property (IP) laws, which most countries have adopted. IP refers to the legal rights that result from intellectual activity in the industrial, scientific, literary, and artistic fields. IP laws generally distinguish among four separate IP regimes, which are targeted at different subject matters: information products (and more generally literary, musical, choreographic, dramatic, and artistic works) are protected by copyrights; the three other regimes (patents, trade secrets, and trademarks) aim at

protecting industrial property (such as inventions, processes, machines, brand names, industrial designs).

It is important to note, from an economic perspective, that IP laws alleviate the “underproduction” problem at the cost of exacerbating an “underutilization” problem. To understand this second problem in the context of information products, we need to refer to another characteristic of information products, namely, their non-rivalness, which refers to the property that their consumption by one person does not prevent their consumption by another person (for instance, the fact that some person listens to the performance of an artist does not reduce the possibility for anyone else in the audience to listen to the same performance). A consequence of this nonrivalness is that the marginal cost of production of information products is zero (i.e., taking the artist’s viewpoint in the previous example, once the show has started, it costs nothing to have one extra spectator viewing it). From the point of view of static efficiency, the price of information goods should therefore be equal to zero. However, because IP laws endow them with some market power, the creators of information products are able to set a positive price, which reduces social welfare by preventing those consumers with a low, but positive, valuation of the information products from consuming them.

In other words, IP laws aim at striking the balance between providing incentives to create and innovate while promoting the diffusion and use of the results of creation and innovation. To do so, IP rights are granted only for a limited period of time and for a limited scope. In particular, copyright protection usually lasts for a number of years (currently, 70 in both the European Union and the United States) after the creator’s death; in terms of scope, copyrights protect only the expression but not the underlying ideas.

Defining Digital Piracy

IP laws are effective only if they are properly enforced and respected. Yet, as far as information products are concerned, one observes a large-

scale violation of the laws protecting them, a phenomenon known as “piracy.” What is striking is that the illegal reproduction and distribution of copyrighted works is not only the act of criminal organizations (so-called commercial piracy) but also the act of the consumers themselves (so-called end-user piracy). (We do not review here factors that influence the piracy decision; one can indeed wonder what motivates such large-scale violation of IP laws by individuals who are normally law-abiding citizens; for a review of the literature on this topic, see Novos and Waldman (2013).)

Commercial piracy does not need much analysis, as the motivation is easily understood: criminal organizations are simply attracted by the high profit margins that the large-scale reproduction and distribution of copyrighted products generate. On the other hand, end-user piracy raises a number of issues that the fast penetration of the Internet and the digitization of information products have made much more pressing. Digital technologies have indeed drastically reduced the cost of making and distributing illegal copies while increasing their quality; thereby, they have deeply modified the interaction between end users, copyright holders, and technology companies. End-user piracy in the digital age, or for short *digital piracy*, is thus a major phenomenon that requires a thorough analysis.

The Basic Economics Analysis: Digital Piracy Decreases Profits

The main consequence of digital piracy is that it seriously limits copyright owners in their ability to control how information products get to consumers. As a result, the availability of digital copies is likely to reduce the copyright owner’s profits. This is the prediction that can be drawn from the basic *theoretical modeling* of piracy (see, for instance, Novos and Waldman 1984, Johnson 1985, and the references in Belleflamme and Peitz 2012). These models simplify the analysis by focusing on the market for a digital product supplied by a single producer. One can justify this assumption by arguing that digital products within

a given category are highly differentiated in the eyes of the consumers; the demand for any product is therefore hardly affected by the prices of other products. Even though the copyright owner acts as a monopoly, he/she faces nevertheless the competition exerted by the availability of (illegal) digital copies. Copies are seen as imperfect substitutes for the original digital product, insofar as their quality is generally lower than the quality of original products. In particular, the quality of copies primarily depends on technological and legal factors, which can be affected by public authorities (through the definition and the enforcement of IP protection) and/or by the copyright owner himself or herself (through technical protective measures). In this setting, it is possible to analyze the copyright owner's decisions about the pricing and the technical protection of original products, as well as public policy regarding IP laws.

The main results of these analyses can be summarized as follows. First, because consumers with a low cost of copying or with a low willingness to pay for quality prefer copies to original products, the copyright owner is forced to charge a lower price (than in a world where digital piracy would not exist). That clearly decreases the copyright owner's profits but increases the surplus of the consumers of original products; moreover, a number of consumers who were not willing to purchase the original product at the monopoly price get now some utility from the pirated copies. As the increase in consumer surplus outweighs the profit reduction, digital piracy results in an improvement of welfare from a static efficiency point of view (like any erosion of market power does). However, the lower profits may reduce the incentives of copyright owners to improve the quality of existing products or to introduce new products on the market; this is detrimental to welfare from a dynamic perspective. Moreover, total welfare may decrease because of a number of avoidable costs that digital piracy entails (e.g., the costs for producers to implement technical protective measures or the costs for public authorities to enforce copyrights).

Looking at the profits of copyright owners, it is an undisputed fact that they started to decrease when end-user piracy started to grow (i.e., around

1999 with the launch of Napster, a peer-to-peer file-sharing service). This was particularly acute in the music industry where physical music sales (that is to say, CDs) dropped significantly. Numerous *empirical studies* (for a survey, see Waldfogel 2012a) have tried to estimate the extent to which this decrease in sales could be attributed to digital piracy. These studies converged on the conclusion, now widely accepted, that digital piracy has “displaced” physical sales (i.e., legal purchases were substituted for, mainly, illegal downloads). However, it is also established that the estimated “displacement rate” is slightly above zero and nowhere near unity, reflecting the observation that the vast majority of goods that were illegally consumed would not have been purchased in the absence of piracy (contrary to what the recording industry would have liked the general public to believe by counting any download as a lost sale).

Very little empirical work has been devoted to the long-term effects of piracy (i.e., to dynamic efficiency considerations). One notable exception is Waldfogel (2012b), who tries to estimate the extent to which digital piracy has affected the incentives to bring forth a steady stream of valuable new products. To address this issue, he uses three different methods to assess the quality of new recorded music since Napster. The three resulting indices of music quality show no evidence of a reduction in the quality of music released since 1999; two indices even suggest an increase. One explanation could be that the digital technologies that have made piracy easier have also reduced the costs of bringing creative works to market and that the latter effect is at least as important as the former.

Reactions of Copyright Owners

In the face of digital piracy and of the reduction of sales, the first reaction of copyright owners was to try and prevent the existing business models from crashing down. As these models were relying on controlled distribution and broadcast channels, the main strategies consisted (i) in pursuing more heavily copyright infringers, (ii) in using

digital technologies as protective measures, and (iii) in lobbying for more restrictive IP laws.

The music industry started the fight against illegal downloading. In 2001, the Recording Industry Association of America (RIAA) obtained the closure of Napster, but the victory proved short-lived as a number of other file-sharing systems (such as Kazaa, LimeWire, and Morpheus) quickly replaced Napster. The industry started then a campaign of litigation against individual P2P file sharers: between 2003 and 2008, legal proceedings were opened against about 35,000 people. The software and the movie industries also engaged in similar legal battles.

As far as technical measures are concerned, a common tactic was to protect digital products through so-called digital rights management (DRM) systems, which inhibit uses of digital content not desired or intended by the content provider. DRM systems were meant to fight digital piracy but also, more generally, to manage how digital products can be used. Well-known examples of DRM systems are the Content Scrambling System (CSS) employed on film DVDs since 1996, so-called “copy-proof” CDs introduced by Bertelsman in 2002 (which could not be played on all CD players and were later abandoned), and the FairPlay system used by Apple on its iTunes Music Store. Such systems were gradually abandoned in the music industry (but are still used in other industries, such as in the case of ebooks).

Finally, lobbying efforts were met with success as stronger copyright laws were passed in a number of countries. In the United States, in 1998, the Copyright Term Extension Act extended the duration of existing copyrights by 20 years, while the Digital Millennium Copyright Act reinforced copyright protection by making it a crime to circumvent the technological measures that control access to copyrighted work. In Europe, a number of EU directives led EU member states to harmonize their national copyright laws in the first half of the 1990s; also, the European Union Copyright Directive (EUCD) of 2001 required member states to enact provisions preventing the circumvention of technical protection measures. In the late 2000s, some countries (led by France and the United Kingdom) passed

so-called three-strikes antipiracy laws, which authorize the suspension of Internet access to pirates who ignored two warnings to quit. Finally, actions were also directly taken against platforms that were hosting and sharing illegal content (the most famous cases being the shutdowns of Napster in 2001, of Megaupload in 2012, and of the Pirate Bay in 2013).

In sum, the first reaction of copyright owners in the face of digital piracy was to enforce and reinforce both the legal and technical excludability of their products. However, these measures turned out to be of little effectiveness and sometimes even counterproductive. On the one hand, technical measures were not only quickly circumvented but they also irritated legitimate consumers, thereby decreasing their willingness to pay for copyrighted products. Zhang (2013) gives an indirect proof by showing that the decision by various labels to remove DRM from their entire catalogue of music increased digital music sales by 10%. To establish this point, she compares sales of similar albums with and without DRM before and after DRM removal; her sample includes a large selection of hits and niche albums, from all four major record labels and from multiple genres.

On the other hand, a number of empirical studies have tried to assess the effectiveness of anti-piracy interventions by governments on the sales of digital products. The results obtained so far are rather mixed. For instance, two papers examine the impacts of French “three-strikes antipiracy law” (known as HADOPI law) introduced in 2009 and reach opposite conclusions: Danaher et al. (2014) find that the law caused a 20–25% increase in music sales in France, whereas Arnold et al. (2014) conclude that the law was ineffective not only in deterring individuals from engaging in digital piracy but also in reducing the intensity of illegal activity of those who did engage in piracy. Similarly, different approaches to estimate the impacts of the shutdown of Megaupload in 2012 lead to contrasting conclusions. Peukert et al. (2013) compare box office revenues before and after the shutdown for two sets of movies with matching characteristics but presenting one main difference: the first set could be accessed illegally through Megaupload, while the second set could

not. Using a quasi difference-in-differences approach, they establish that the shutdown of Megaupload did not have any positive impact on box office revenues across all movies in the sample. In contrast, Danaher and Smith (2013) exploit the fact that there exists cultural variation across countries in the degree to which Megaupload was used as a channel for piracy. They show that digital movie revenues for two studios were 6.5–8.5% higher over the 18 weeks following the shutdown (across 12 countries) than they would have been if Megaupload had continued to operate.

Even if further empirical research is called for to refine the analysis of the effectiveness of anti-piracy measures, some of the existing results suggest that digital piracy may also have some positive impacts on the copyright owners' profits, which may balance the negative "business-stealing" effect. We therefore turn to a second set of economic models that present piracy under a more favorable angle.

Further Developments: Digital Piracy May Increase Profits

A number of theoretical studies (see Peitz and Waelbroeck 2006, and the references in Belleflamme and Peitz 2012) have demonstrated the positive effects that piracy may have on the profits of copyright owners. Three mechanisms have been identified. First, illegal copies of a digital product can play a *sampling* role by attracting consumers and driving them to purchase a legitimate copy later. This argument is based on the observation that digital products are complex "experience goods"; that is, consumers do not know the exact value that they attach to particular digital products before consuming them. Buying a legitimate copy may thus appear as risky, which inevitably reduces demand. However, if an illegal copy can be accessed free of charge, consumers may learn their valuation of the product, and if the latter is large, they may want to purchase the legitimate product (which is often, as argued above, of a higher perceived quality).

The empirical results of Zhang (2013) are consistent with this theory. As we noted above, her analysis shows that the removal of DRM had a positive impact on digital music sales; yet this impact was much more pronounced for niche than for hit albums, which suggests that more flexible sharing increased sales because it lowered search costs (which are arguably larger for lower-selling than for top-selling albums).

The second mechanism originates in the fact that many digital products generate *network effects*; that is, the attraction of the product increases with the number of consumers of that product. This is so with software (the wider the community of users, the easier it is to exchange files, and the larger the supply of complementary products) or with cultural products (whose popularity increases with word of mouth). As it is the cumulated number of consumed copies that matters and not whether these copies are legitimate or not, digital piracy contributes to increase the willingness to pay for legitimate copies. An anecdotal evidence of the importance of this mechanism can be found in the reaction of one of the directors of the series "Game of Thrones" (produced by the American premium cable network HBO) when interviewed about the huge illegal downloading of the first episode of the third season (estimated to over one million times in the space of 24 h); he basically stated that the series benefits from piracy because it feeds the "cultural buzz" that allows this kind of program to "survive" (see <http://tinyurl.com/lu93q6j>).

Finally, the third mechanism, called *indirect appropriation*, resembles the second by invoking the fact that piracy can increase the demand for goods that are complementary to the pirated content; the producer is then able to capture indirectly the value that consumers attach to the pirated good. This goes, for example, for increasing ticket sales for the concert of an artist, whose popularity may be partly due to a large base of fans consuming pirated copies of this artist's songs. Mortimer et al. (2012) provide some empirical evidence along these lines; combining detailed album sales data with concert data for a sample of 1,806 artists on the period 1999–2004, they find that digital piracy reduced sales but increased live

performance revenues for small artists (the impact for large, well-known artists being negligible).

Perspectives

The presence of these potential positive impacts of piracy and the inability to preserve the existing business models drove the content industries to experiment with new solutions. Because it had been the first to be hit by digital piracy, the music industry also took the lead in terms of innovative business models. The first answer to falling CD sales was to move the distribution of music online. At the forefront was the iTunes Music Store operated by Apple, which opened in 2003. These legal online channels for digital music allowed consumers not only to find and download music as easily as via illegal channels but also to start buying individual tracks instead of being forced to buy albums. Koh et al. (2013) suggest that the latter possibility induced a new way of consuming music, which contributed to weaken the negative effect of online music piracy on physical music sales; according to their empirical assessment, it is the legal sales of online music and not digital piracy that displaced physical music sales after 2003.

In the same vein, Aguiar and Martens (2013) conclude that the online legal sales of digital music (through online stores such as iTunes or via streaming services such as Spotify) do not seem to be displaced by illegal downloading; the opposite may even occur. To establish this result, they analyze the behavior of digital music consumers on the Internet. They use direct observations of the online behavior of more than 16,000 Europeans. The main result of their analysis is that illegal downloading has no effect on legal consumption. At best, this effect is positive: a 10% increase in clicks on illegal download websites leads to an increase of 0.2% in clicks on legal purchase websites. Piracy does not induce any displacement of the legal music purchase in digital format; it might even slightly boost sales. (People in the sample have willingly accepted to be observed. This introduces two potential biases: on the one hand, it is quite likely that the “heavy

downloaders” have refused to be part of the sample; on the other hand, individuals in the sample may have changed their behavior knowing that they were observed. We must also keep in mind that in the relevant time period, while increasing, online music sales accounted for only a small fraction of the overall revenues of the music industry and that physical sales have been shown to suffer from piracy (5% in 2010 and 8% in 2011 according to IFPI).)

New business models in the music industry also offer market solutions to increase revenues from the segment of consumers with a low willingness to pay for music and with, therefore, a high disposition to digital piracy. As Waelbroeck (2013) describes it, the streaming services (such as Spotify or Deezer) are based on a “freemium” model, which combines free and premium (i.e., paying) services. The objective is to attract users with the free offering and, later, “convert” them to paying subscribers. This objective can be reached through different ways: the premium offering can include additional “mobility” (e.g., the possibility to access playlists on various devices, such as a computer, a tablet, or a smartphone), better sound quality, a wider library of titles, or the removal of ads.

Markets for information products are undergoing major changes due to technological innovations, which triggered digital piracy and, partly as a response, new business models. As exemplified above, in this changing landscape, some research suggests that consumer behavior exhibits several interesting features. Whether these features are stable over time and space is an interesting area for future research. Such an understanding is necessary to evaluate the impact of digital piracy on markets for information products and to develop successful new business models. It is also necessary to propose appropriate public policy responses.

Director, Aaron

Robert Van Horn

Economics Department, University of Rhode Island, Kingston, RI, USA

Abstract

Aaron Director (1901–2004) is often recognized as the founder of Chicago law and economics and a leader in establishing the postwar Chicago School. This biographical essay explores Director's early life, that is, his high school and college years, and his principal contributions to the postwar Chicago School.

Biography

Aaron Director (1901–2004) is often recognized as the founder of Chicago law and economics, the pioneer “in reorienting antitrust policy along free-market lines,” and a leader in establishing the postwar Chicago School (see Bork (2004), Posner quoted in Bernstein (2004), and Samuelson (1998)). Through his work at the University of Chicago, Director had a profound influence on colleagues of his own generation, such as Edward Levi and George Stigler, and, on later luminaries, such as Lester Telser, Richard Posner, Ward Bowman, John McGee, Robert Bork, and Reuben Kessel.

Director's colleagues lauded his analytical abilities and joshed about his lack of publications. His long-time colleague, George Stigler, said, “[Most] of Aaron's articles have been published under the names of his colleagues,” (<http://chronicle.uchicago.edu/040923/obit-director.shtml>). Access Date 8/20/09) and Sam Peltzman, a colleague and

Robert Van Horn is an assistant professor of economics at University of Rhode Island. His research has primarily focused on the history of the postwar Chicago School. He is a coeditor, along with Philip Mirowski and Thomas Stapleford, of *Building Chicago Economics* (Cambridge University Press, 2011). *History of Political Economy* and *Journal of the History of the Behavioral Sciences*, among others, have published his work. More information can be found at: <http://www.uri.edu/faculty/vanhorn/index.htm>.

student of Director, observed, “His life was long, his vita was short” (2005, p. 313). Edward Levi, Director’s long-time Chicago Law School colleague, wrote: “[Director is] a self-effacing but determined scholar who has never lost the integrity of his own discipline [of economics] as he has brought this discipline to bear on the problems of [the field of law]” (1966, p. 3).

Shortly after Director’s death, prominent newspapers paid tribute to his life. *The New York Times* described Director as “a theoretician who broadly influenced scholars’ thinking about anti-trust law” (Douglas 2004). *The Washington Post* referred to Director as a “celebrated free-market economist who helped unite the fields of law and economics and mentored several generations of scholars” (Berstein 2004). The University of Chicago also celebrated his life. Its law school held a retrospective. Stephen Stigler and Sam Peltzman each gave memorial lectures, which were published in the October 2005 issue of the *Journal of Law and Economics* – a journal Director helped to found (see Stigler (2005); Peltzman (2005)).

The following pages on Director illuminate two periods of his life. First, I describe Director’s high school and college years (1918–1924) (this section mainly draws from Van Horn (2010)). This period of Director’s life helps us better appreciate his later contributions to Chicago law and economics. Next, I examine the time period during which Director made his most significant contributions to what would become Chicago law and economics (1946–1964) (this section mainly draws from Van Horn (2009, 2011) and Van Horn and Klaes (2011)). While not covered in detail below, over the next couple of years, I plan to research the interim period). I primarily focus on the evolution of Director’s own views during two projects he headed, the Free Market Study (1946–1952) and the Antitrust Project (1953–1957), and then very briefly explore how Director influenced some of the later principals of the Chicago law and economics movement through his work during the Antitrust Project.

High School and College Years

At the age of 12 or 13, Director along with his family emigrated from Charterisk, Russia, to

Portland, Oregon. (Most of what will probably ever be known of Director’s life in Russia is found in Rose Friedman’s (his sister’s) autobiography. See Friedman and Friedman (1998, pp. 2–6).) They were Jewish. Director would have quickly learned that political and social freedoms had their limits in the United States (the description of Portland in the following paragraphs draws heavily from MacColl (1979) as well as from James Breslin (1993), Mark Rothko’s biographer). Although Portland had an established reputation as a progressive city, reactionary politics dominated the city in the 1910s. In 1917, about 85% of Oregon’s residents were native born and overwhelmingly White Anglo-Saxon Protestants (WASPs) (according to MacColl, “the ‘covered wagon complex’ was still prevalent” at this time, partly because the pioneers’ recent descendents had “fought to preserve [their] purity in the face of an influx of foreign immigrants” (1979, p. 139)).

During WWI, to espouse a radical position in Portland was “quite dangerous” (Breslin 1993, p. 39). Across the nation, assimilation – or “Americanization” – became more coercive. The 1917 Espionage Act “effectively made political dissension a crime,” and the 1918 Sedition Act stated that anyone who “spoke disparagingly of the U.S. government, its Constitution, or its flag” would serve 20 years in prison (Breslin 1993, p. 39). The jingoism of WWI reached an unrivaled level in Portland, which “became the patriotic center of the Northwest,” according to Kimbark MacColl. Because of their international ties, Portland Jews, many of whom were recent immigrants, became the target of “super-patriots” and thus needed to exercise uncommon circumspection. (This is not to say that all Eastern European Jews were suspect. For example, Ben Selling, an Eastern European Jew and successful businessmen, was a community leader. During WWI, he demonstrated his patriotism by buying \$400,000 worth of Liberty Bonds (MacColl 1979, pp. 50–51).)

After WWI ended, Portland’s Jewish immigrants faced discrimination of a different nature. Rumors spread across the United States that a “diabolical, radical conspiracy” against the US

government was brewing (MacColl 1979, p. 156). In Portland, without the demonized groups of WWI (e.g., the “Huns”), the “reds” became the new demons, and “many of the ‘reds’ happened to be Jewish” (Breslin 1993, p. 40). According to MacColl, “there was actual fear, even in Oregon, that a Red revolution might begin,” patterned after the recent Bolshevik revolution. Consequently, Oregon passed strong antiradical legislation in January 1921, the month Director graduated from high school. Supporting the law, *The Oregon Journal* wrote, “We must hereafter have an Americanized America” (MacColl 1979, p. 157).

In this environment of ongoing coerced conformity, Director received his education. Director went to Lincoln High School in the spring of 1918. Here Director formed a close bond with several Jewish friends, including Mark Rothko (the famous painter).

Even though Director came from a family that was somewhat better off than the poorest Jewish families, Director, at Lincoln High School, faced tensions arising from ethnic and class differences. Of the 900 students at Lincoln, probably no more than 10% were Jewish (Breslin 1993, p. 36). The majority, WASPs, exerted considerable control at Lincoln. Overseeing the membership in social clubs and athletic teams, WASPs excluded Jews. Director’s friend, MacCoby, complained: “Anyone who has a name ending in ‘off’ or ‘ski’ is taboo and branded a Bolshevik” (quoted in Breslin 1993, p. 36). Slurs were not uncommon: “Jewish clannishness inspired bad jokes about the close friendships...between Director and MacCoby” (Breslin 1993, p. 36).

In Portland, both inside and outside of high school, Director faced a milieu fraught with discrimination. Director had views contrary to those of the establishment of Portland and many of the WASPs at Lincoln. During his senior year, when he served as editor of the January 1921 issue of *The Cardinal*, Lincoln High’s school magazine, Director responded to the majority views with caution and prudence. As editor, Director compiled an editorial section of anonymous editorials. (In the following paragraphs, unless otherwise indicated, all quotations come from the January 1921 issue of *The Cardinal*. See (CARD 1921).)

Since Director was the head editor and since the editorials express a consistent worldview sympathetic to the hardships of immigrants, it seems reasonable to assume that the worldview expressed in the editorials was consistent with Director’s own.

The editorials portrayed a world of not only overt racial prejudice and zealous patriotism but also ubiquitous political corruption and economic evils. The editorials detested the myopic view of the immigrants presented in the newspapers. They claimed that the newspapers only concentrated on “the faults” of immigrants and offered hasty generalizations. The editorials dismissed the effort to determine who was American and who was not as arbitrary classification, and they suggested that the economic evils stemmed in part from a “maladjusted industrial system” (p. 62).

According to the editorials, hope for a cure rested not with material growth and technological progress but with education. They stated: “It is the teacher who is largely responsible for the type of man and of woman that will represent America in the future” (p. 62). Education, they suggested, would alleviate social and economic maladies and remedy the ills of jingoism and bigotry. They challenged their classmates of Lincoln: “The Hungarian, the Russian, the Jew, the Pole; all can teach us something. We must derive benefit from the good that is in them, and show them the good that is in us. Thus a finer and nobler civilization may be evolved” (p. 63). Moreover, they disputed the idea that obeying the law, fighting for one’s country, and being unquestioningly loyal to one’s government were among the necessary conditions to be American. Instead, the editorials maintained that “Americanism” included “progress, reform, and the enlightenment of the human race” (p. 63).

The editorials suggested that social and economic problems could be identified by a vigilant and inquiring mind and that significant reform would only be possible if unrestrained questioning of not only creed and tradition but also public policy and social norms was allowed. The editorials extolled a vision of a heroic reformer – a broad-minded and liberal reformer who possessed the courage to confront both

political corruption and economic evils and had the ability to see the good in all races and understand the true meaning of what it means to be an American (the editorials use the term “liberal educators” to imply free-thinking educators who are without prejudice and who are in favor of progress and reform).

The editorials expressed an idealistic attitude, but not a serious program for reform. Although Director was an iconoclast and not afraid to challenge the prejudice and problems of Portland, he was no social rebel. When Director criticized the establishment, it tended to be with cautious circumspection or with harmless sarcasm; he never directly attacked an individual or an identified group of individuals.

Upon graduation in January 1921, Director left Portland for Yale University. According to Oren, “The public high school mythology that held that America’s great universities were temples of learning attracted the Eastern [Europeans Jews] to ‘worship’ at Yale” (1985, pp. 27–28). The spires of the great university beckoned Director. Ironically, however, the university system that inspired hope in the Eastern Jewish community was slowly excluding them. Director and Rothko entered Yale at a time of heightened anti-Semitism in the nation. The Ivies proved to be one of the primary anti-Semitic battlegrounds in the country, and Yale was one of the least friendly places to Jews.

In the 1921–1922 academic year, Yale reconsidered its admissions policy in order to decrease the percentage of Jews enrolled. This most likely resulted in Director losing his tuition scholarship after his first academic year. Around Yale’s campus, Director also faced discrimination. The Protestant upper classes controlled the social clubs, athletic teams, fraternities, and senior societies, all of which tended to exclude Jews. Many of Yale’s social groups favored graduates of prep schools and students from wealthy families.

Because Director received very little financial help from his family and needed to work his way through, Director, like Rothko, most probably waited tables in the dining hall when he started at Yale. According to Oren, “Students identified as poor, students who had to perform a ‘low class’

job such as waiting on tables. . . landed in almost inescapable social damage” (1985, p. 68).

Director decided to pursue a Ph.B. in “progressive politics.” Putting his major to use before leaving Yale and fulfilling his high school ambitions to be a newspaper editor, Director attacked Yale’s establishment in an underground newspaper. In the spring of 1923, Director along with Mark Rothko and Simon Whitney produced *The Yale Saturday Evening Pest* – an underground newspaper. The *Pest* was a stinging reaction to life at Yale and society at large, and, according to Oren, its “depictions of Yale life” were by and large “fair representations of reality” (p. 90). The *Pest* sheds light on Director’s philosophy of life at this time.

Disillusioned by the reality of Yale, Director and the other editors claimed that they saw the empty lives of Yale’s undergraduates for what they were. In an issue entitled, “False Idols,” the *Pest* observed, “The Yale undergraduate is an idolater. He is as senseless as [anyone] who prays to a totem pole, or [anyone] who mumbles in fear before a meteorite. At least the meteorite has come down from the sky. . .” (SEP, March 17, 1923). The idols of Yale included: athletics, extra-curricular success, social success, the opinion of the majority, and grades. The first received by far the most criticism in all the issues of the *Pest*. The “god” of athletics was “low-browed, but husky, with muscular arms and long legs whose pedal extremities carry a powerful kick. We talk of erecting a statue of him, in the shape, appropriately, of a bulldog.” The worship of this god, which demanded greater veneration at Yale than education, involved participation for some (SEP, February 23, 1923), but, according to the *Pest*, it meant “lung athletics” for the majority in the “bleacher seats.” In the spirit of Veblen’s *Higher Learning in America*, the *Pest* railed, “The present athletic system injures our bodies and narrows our minds, making us insufferable bores to any intelligent man” (SEP, March 17, 1923). About the idols at Yale, the editors of the *Pest*, like Old Testament prophets, proclaimed: “False gods! Idols of clay!”

The *Pest* identified the cause of the “fundamental evil” that afflicted Yale to be “. . . the

rusty condition in which the mass of undergraduates have allowed their minds to molder” (SEP, March 17, 1923). Hope for a cure could not be found by turning to the powers that be at Yale. The *Pest* maintained that universities were ultimately run by merchants, and this merely contributed to the large population of unthinking undergraduates. For the *Pest*, because Yale failed to educate thinking men who could see through bigotry and jingoism, Yale was partly to blame for anti-Semitism and other forms of prejudice and racism in the United States.

Despite Yale being part of the cause of larger social problems, the *Pest* did not prescribe reforms for Yale. Instead, it sought to disillusion Yale undergraduates, causing them to see their own unthinking for what it was. For the *Pest*, “destructive criticism” was the key to freedom from unthinking – hence its masthead with the provocative slogan: “The Beginning of Doubt is the Beginning of Wisdom.”

Destructive criticism promised to show unthinking undergraduates their “uselessness in the world” and the “emptiness of their ambitions” and thereby be life changing (SEP, March 3, 1923). It also promised to be informative. Destructive criticism – if it was thoughtful, sincere, and purposeful – helped others to see the root of social and economic problems and see how bigotry and racism prevented progress. Per the *Pest*, change came from the ground up, starting with the individual. In sum, the *Pest* represented Director’s high school vision of the heroic reformer; Director and the other editors saw themselves as broad-minded educators who challenged the root of economic evils and racism and thereby awakened in others the capacity and vision to remedy these serious social and economic problems.

Yale was a formative place in Director’s life. The entrenched elitism to which Director reacted and the “unthinking” life at Yale and in society at large that Director lambasted shaped his outlook on life. Director had come of age as a skeptic and an individualist. He rejected governing structures as instruments of the established business class that could not be trusted to implement meaningful reform. In doing so, he foreshadowed his distrust

of government intervention into the economy that informed his work in economics in the 1950s. While at Yale, rather than supporting administrative bodies and student organizations, Director championed individuals like himself or an elite group of individuals like the editors of the *Pest* who could transcend the “pestilence of unthinking” through relentless questioning of “creeds and traditions.” Director praised those who, like the heroic educator, could rise to the occasion against the powers that be and challenge prejudice and social injustice.

Director remained a reformer for decades to come. His vision of the heroic educator led him to head the Portland Labor College (1925–1927). Later, it arguably led him to the University of Chicago in 1946.

The Roots of Chicago Law and Economics

Although Director made his seminal contributions to Chicago law and economics while at Chicago from 1946 to 1964, he studied at Chicago from 1927 to 1934, pursuing a Ph.D. Initially, Director worked with Paul Douglas; they authored *The Problem of Unemployment* in 1931. However, by 1932, Director, according to Douglas, fell under Knight’s influence (VPML, Douglas to Frank H. Knight, 5 January 1935, Box 79, folder “Chicago Dept. of Econ., Douglas & Knight”). Thereafter, Director gravitated toward Henry Simons, who became, according to Ronald Coase (1998, p. 602), his “best friend” and “considerably influenced Director’s views.” In 1933, Director published a pamphlet, *Economics of Technocracy*, demonstrating his affinity for price theory for the first time.

In 1934, when the University of Chicago refused to renew his teaching contract, Director went to work in the Treasury Department in Washington, DC (VPML, H. A. Millis to Viner, 31 January 1934, Box 79, folder “Chicago University Department of Economics, Millis”). Then, in 1937, Director traveled to England to conduct research for his dissertation on the quantitative history of the Bank of England. However, the Bank unexpectedly thwarted his efforts, and Director never completed his thesis. While in England, Director became associated with Arnold

Plant and Lionel Robbins and befriended Friedrich Hayek. After attending one of Hayek's seminars, Director considered Hayek his teacher. Once WWII commenced, Director returned to Washington D.C. and worked for many different agencies. For example, he joined the Brookings Institution, where he wrote a book with C. O. Hardy in 1940 entitled *Wartime Control of Prices*.

While in Washington, Director became one of Hayek's political allies and supported Hayek's intellectual crusade to countervail collectivism (i.e., Keynesianism, institutional reformism, and socialism). He helped to persuade the University of Chicago Press to publish Hayek's *The Road to Serfdom* and wrote a laudatory review of it (Director 1945).

Near the end of the war in 1945, Hayek and Simons encouraged Director to return to Chicago to lead a project that would be called the Free Market Study (FMS). The FMS was primarily the product of the efforts of Hayek. In April 1945, when on tour in the United States promoting his recently published *The Road to Serfdom*, Hayek met with Harold Luhnow, head of the Volker Fund – a Kansas City corporation heavily involved in right wing funding in the postwar period. Luhnow wanted Hayek to write an American version of *Road* and offered him money to do so. The two men agreed that the Volker Fund would finance an investigation of the legal foundations of capitalism and that a product of this investigation would be *The American Road to Serfdom*. The two also agreed that Hayek could outsource this investigation.

Hayek convinced the Volker Fund to allow him to subcontract the project to Simons and Director. Since Simons viewed the liberal doctrine as withering and the collectivist doctrine (i.e., socialism and institutional reformism) as burgeoning, he envisioned the project as a way to reinvigorate the liberal doctrine in order to countervail collectivist doctrine. Simons drew up two memoranda, Memorandum I and Memorandum II, the latter being a concise, executive version of the former (SPRL, box 8, file 9). Simons wholeheartedly endorsed Aaron Director as the leader of this project. Simons feared that without an organized

effort to revive liberalism, it would “be lost,” and he believed that Director's leadership would help to engender a liberal stronghold at the University of Chicago in the immediate post-WWII period (SPRL, Memorandum I, undated, box 8, file 9).

Bringing Director back to the University of Chicago meant a great deal to Simons. Indeed, in 1939, Simons had written: “[I]n spite of my efforts and good intentions of other people, I have been, *qua* economist, alone since Aaron left. Certainly I am worth more to the University with Aaron around than without him” (quoted in Van Horn (forthcoming)). Director responded favorably to the proposed project. He also drafted a proposal for the project, which he called “the Free Market Study.” Director's plan delineated the benefits and limitations of the free market and enumerated the departures from the free market at the close of WWII – including: barriers to entry (such as patents and tariffs) and government controls (such as price controls). In keeping with Hayek and Luhnow's agreement, Director also listed numerous policies that needed to be examined to return to a free-market economy, including antitrust policy and corporate policy. In many ways, Director's list echoed Simons' *Positive Program*; for example, Director called for limitations on corporate size and for federal incorporation to be required.

After many trials that have been detailed elsewhere, by July 1946, Director agreed to head the FMS, which would be housed at the Chicago Law School. Director, however, would have to return to Chicago and lead the project without his dear friend Simons; Simons committed suicide on June 19, 1946 (see Van Horn (forthcoming)). Indeed, part of the reason Director returned to Chicago was to carry on the legacy of Simons.

In October 1946, Director assumed leadership of the FMS (for background and more information about the study, see Van Horn and Mirowski (2009), and for more information on the Free Market Study and the Antitrust Project, see Van Horn (2009) and Van Horn and Klaes (2011)). Director and the study's members (Milton Friedman, Frank Knight, Edward Levi, Garfield Cox, and Wilbur Katz) convened regularly in order to discuss and debate. The FMS's task had a sense of urgency because of the perceived strength of

collectivist forces. Hayek conveyed this urgency when he wrote: “The intellectual revival of liberalism is already under way. . . . Will it be in time?” (1949, p. 433).

At the second meeting of the study, Director distributed a research proposal entitled: “A Program of Factual Research into Questions Basic to the Formulation of a Liberal Economic Policy.” As Director’s title suggests, the topics the study decided to investigate were not chosen purely because of theoretical concerns: political necessity was a factor. By empirically investigating the facts taken for granted by both liberals and their opponents, Director believed it would be possible to develop a more robust liberal policy to counter collectivism and thereby bring about policy changes in the United States.

The FMS decided to mainly concentrate its efforts on issues concerning industrial monopoly and corporations. It hired researchers, for example, Warren Nutter (1951), to do empirical work on the issue of industrial monopoly and brought like-minded visiting scholars to Chicago. During the early years of the FMS (1946–49), Director, Friedman, and others were uncertain how to reconstitute liberalism in order to best combat socialism and other forms of collectivism. Like Director during his 1947 Mont Pelerin address, they, in many ways, echoed the beliefs of classical liberals, expressing concerns about concentrations of power, including industrial monopoly.

One year after the FMS commenced, Director agreed to be a charter member of the Mont Pelerin Society in 1947. Led by Friedrich Hayek, liberals turned to organizing an intellectual movement, the Mont Pelerin Society, a transnational institutional project that sought to reinvent a liberalism that had some prospect of challenging collectivist doctrines ascendant in the immediate postwar period. The society enabled its members – liberals from America, many who represented the Chicago School, and Europe – to debate and offer each other mutual support. A crucial objective of the society was to understand the legal foundations necessary for effective competition – that is, how to create a competitive order. The society and the FMS were joined at the hip at birth (Van Horn and Mirowski 2009). The fact that both sought to

investigate a number of legal and policy areas in order to move toward effective competition is just one indication of their conjoined birth. Director’s involvement in the society indicates his determination to see the liberal doctrine reconstituted. In the opening session of the 1947 inaugural meeting, which was on the competitive order, Director gave one of the addresses (at the first meeting, its members, besides debating the issue of “‘Free’ Enterprise or Competitive Order,” debated “The Future of Germany,” “The Problems and Chances of European Federation,” “Liberalism and Christianity,” and “Modern Historiography and Political Education”). His address sheds further light on his views regarding concentrations of business power at this time.

In his address, Director claimed that authority had either supplanted individualism or ominously threatened to do so. Director maintained that state intervention had nearly destroyed the competitive order because liberals lacked solutions to resolving conflicts between social interests and the results of free enterprise. As a remedy Director advocated for a reconstituted liberalism. (The following paragraphs draw from the records of the 1947 Mont Pelerin meeting, Liberal Archives, Ghent, Belgium. See MPS1947LA.)

In keeping with Simons, Director steadfastly believed that the liberal doctrine needed, above all else, to champion freedom by promoting the dispersion of power necessary for a competitive order. Notably, Director observed that a substantial amount of monopoly power existed in the economy. To create a viable competitive order, Director, like Simons, advocated state action on three fronts: (1) preventing private monopoly, (2) controlling combinations among workers and businesses, and (3) providing monetary stability. Given the focus of the FMS and given Director’s contributions to law and economics partly stemmed from his work on antitrust law, we shall restrict ourselves to addressing only (1) and (2).

Regarding industrial monopoly, although Director maintained that international trade normally provided a check on industrial monopoly, he admonished that this was an insufficient check. Indeed, Director blamed England’s

overconfidence in the ability of international trade to eliminate business monopoly as a significant reason for the relatively large number of business monopolies in England. Director expressed qualified praise for the enforcement of American antitrust law and suggested that more vigorous antitrust was necessary to address the substantial amount of monopoly power in America. Additionally, for Director, policy reform needed to target patent law and policy measures needed to address the inequality of income and inequality of wealth that stemmed from monopoly power.

Director asserted that radical corporate reform also needed to be undertaken. He maintained:

The unlimited power of corporations must be removed. Excessive size can be challenged through the prohibition of corporate ownership of other corporations, through the elimination of interlocking directorates, through a limitation of the scope of activity of corporations, through increased control of enterprise by property owners and perhaps too through a direct limitation of the size of corporate enterprise. (Quoted in Van Horn (2009))

Like Director during his 1947 Mont Pelerin address, from 1946 to 1949, the members of the FMS echoed in many ways the classical liberal tradition by expressing concerns about concentrations of power. However, during the latter half of the project (1950–1952), a reconstituted liberalism emerged. This marked a crucial shift in attitude toward concentrations of business power, which dramatically changed the way both corporations and patents would be understood by the postwar Chicago School. By 1950, business monopoly was no longer viewed as a relatively ubiquitous and powerful phenomenon in the United States; rather it was seen as relatively un-pervasive and benign because the “corrosive effects” of competition would always and eventually undermine it (Director 1950). By 1951, large corporations were no longer considered harmful to competition because of their market power, but rather another aspect of a competitive market (Director 1951). Consequently, for Director, concentrated markets tended to be efficient, regardless of the size of business.

As the FMS ended, the Antitrust Project began. Director headed the project and Edward Levi

assisted. The members included John McGee, William Letwin, Robert Bork, and Ward Bowman. The Antitrust Project focused on issues of monopoly, select areas of antitrust law, and the history of the Sherman Act (for a list of the articles and books that the Antitrust Project published and that it caused to be published, see Priest (2005, pp. 353–54)). Under Director, the Antitrust Project produced a prodigious amount of scholarship; the topics included: tying arrangements (Bowman 1957), predatory pricing (McGee 1958), trade regulation (Director and Levi 1956), and the Sherman Act (Bork 1954). The Antitrust Project investigated these topics in the light of the conclusions of the FMS. Moreover, in the spirit of the FMS’s attempt to influence policy, it investigated these topics with a critical eye toward United States antitrust law precedent, and many of the conclusions of the Antitrust Project contravened the conclusions of the courts. In 1954, for instance, Bork, in contrast to Director’s classical liberal concern in 1947 about the excessive size of corporations and their concentrated economic power, maintained that “[vertical mergers added] nothing to monopoly power” (p. 195). This Chicago reconstituted-liberal position suggested, therefore, that vertical mergers should always be legal. Consequently, Bork suggested that one aspect of antitrust law precedent, which required an investigation of motives of a vertical merger in order to make a determination of its legality, was not only extraneous but also erroneous.

Bork’s article fell under the Antitrust Project’s umbrella article and manifesto, “Trade Regulation,” by Director and Levi, which they published in 1956. In this article, Director and Levi demonstrated skepticism about the extension of monopoly power through the use of exclusionary practices, such as tying arrangements, and a concomitant disdain for adjudication or legislation that regarded these practices as *per se* deleterious or as *per se* illegal (Packard 1963, p. 56). Director and Levi suggested that exclusionary practices were no worse than harmless price discrimination and served as either competitive tactics equally available to all businesses or means of maximizing returns on an established market position. Thus, Director and Levi maintained

that when the courts deemed it necessary to consider the legality of an exclusionary practice, they should utilize a rule of reason analysis, not a per se approach.

It is important to appreciate that even though Director published little during the course of the Antitrust Project, he substantially influenced its members through his role as an educator. Most of the members of the Antitrust Project later acknowledged Director's substantial influence on their views and his import for the development of their scholarship. For example, in his book *Patent and Antitrust Law*, Bowman reported: "The analysis on which the conclusions of this work are based is derived from years of association with colleagues, from whose oral and written contributions I have long borrowed heavily. . . . I am especially indebted to professors Aaron Director, Robert H. Bork, [and] John S. McGee" (1973, p. vii).

It is also important to acknowledge that the Antitrust Project served to train and educate members of the generation that would help to lead the law and economics movement in the United States. Director educated lawyers, including Ward Bowman and Robert Bork, who would be at the vanguard of the Chicago law and economics movement in the 1960s and 1970s. Many of these lawyers acquired jobs in other law schools. In the case of Bork and Bowman, they both found positions at the Yale Law School. While at Yale, Bork and Bowman played a crucial role in the Chicago law and economics movement in the 1960s and 1970s. Along with Richard Posner and other Chicago lawyer-economists, they helped Chicago law and economics become one of the dominant schools of jurisprudence in the 1980s (for a detailed look at the rise of Chicago law and economics, see Duxbury (1995) and Teles (2008)).

Until he left the Chicago Law School in 1965, Director taught antitrust law and price theory in the law school, founded the *Journal of Law and Economics*, engaged law school faculty – especially Edward Levi and Walter Blum – and mentored graduate students of economics. In 1965, Director moved to Los Altos, California. He worked at the Hoover Institute and Stanford University, from

where he would retire. Director died September 11, 2004, at the age of 102.

Impact and Legacy

In leading the FMS, Director, alongside a small group of like-minded liberals, critically questioned a number of the fundamental tenets of the classical liberal tradition in order to create a more robust liberal doctrine to counter the intellectual influence of collectivism. In leading the Antitrust Project in the 1950s, Director sought to reorient antitrust policy along free-market lines. To do so, he questioned and analyzed some of the fundamental tenets of status quo antitrust policy in the light of the reconstituted liberalism that emerged from the efforts of the FMS. In doing so, Director oversaw the emergence of a prodigious amount of scholarship in the 1950s and mentored many of the later leaders of the Chicago law and economics movement.

The perspectives Director developed during his youth – his belief in the individual or an elite group of individuals as the catalyst for social change, his distrust of governing structures, his faith in the heroic educator, and his adherence to the skeptical philosophy of H. L. Mencken – were not abandoned after he studied Chicago price theory and came to champion liberalism. Highlighting the importance that "destructive criticism" played in Director's work at the Chicago Law School, one Chicago Law School graduate commented that Director "washed all preexisting" antitrust doctrine in "cynical acid" (Liebmann 2005, p. 18). Through his leadership of the Free Market Study, the Antitrust Project, and the Law and Economics Program, Director was a principal of the postwar Chicago School and the founder of Chicago law and economics, not because of his ability to publish and propagate ideas like his brother-in-law Milton Friedman, but because he played an indispensable role educating the next generation of luminaries in the Chicago School. According to one former law student, "To me [Director's] most important contribution... is much less tangible... He developed and reinforced in his students a state of mind without

which much of what they have done would not have been done or would have been done less well” (quoted in Kitch 1983, p. 184). The perspectives of Director’s youth motivated and empowered his postwar efforts at Chicago.

Discrete Choice Models

Patrice Bougette

Department of Economics, Université Côte d’Azur, CNRS, GREDEG, Nice, France

Abstract

Discrete choice models (DCM) have been essential in modeling agents' decision-making behavior. Empirical analysis in law and economics uses therefore such a method. This essay summarizes the definition and the different types of DCMs.

Synonyms

[Qualitative choice models](#)

Definition

Discrete choice models (DCM) describe the behavior of individuals' choices among discrete available alternatives. Decision makers can be consumers, firms, authorities, and any other decision-making unit, and the alternatives represent competing products, courses of action, or any other options over which choices must be made (Train 2009). Examples are decisions about buying a new automobile (individual), allowing a merger (competition authority), entering a new market (a firm), marital status, family size, transport choice, and so on (e.g., Henscher et al., 2005).

Random Utility Models (RUM)

Economics and psychology models often explain observed choices by using a random utility function. The utility of a specific choice can be interpreted as the relative expression of her preferences with respect to the other alternatives available within a finite choice set. The individual is assumed to choose the alternative for which the associated utility is the highest. However, as certain components of utilities are not known to the researcher with certainty, they are therefore treated as random variables. When the utility function contains a random component, the individual choice behavior becomes a probabilistic process (for a historical perspective, e.g., McFadden, 2001).

The random utility function of individual i for choice j can be decomposed into deterministic and stochastic components:

$$U_{ij} = V_{ij} + \varepsilon_{ij},$$

where V_{ij} is a deterministic utility function (i.e., contains all the measured characteristics), generally assumed linear in the explanatory variables, and ε_{ij} is an unobserved random variable that captures the factors that affect utility that are not included in V_{ij} (the error term).

Different Classes of DCMs

Different assumptions on the distribution of the errors – ε_{ij} – give birth to different classes of DCMs. First, logit and nested logit are derived under the assumption that the unobserved portion of utility ε_{ij} is independently and identically distributed (iid) with the extreme value distribution and with a type of generalized extreme value, respectively (McFadden, 1974). Nested logits include different levels of choice.

One important property of the general logit model is known as the *Independence from Irrelevant Alternatives* (IIA). The ratio of any two probabilities depends exclusively on the attributes of the two alternatives concerned and is therefore independent of the number and nature of all other alternatives that are simultaneously considered. For instance, the introduction of a new alternative alters the probabilities of all outcomes in

the same proportion, leaving the ratios unchanged. Thus, the IIA property implies proportional substitution. One limitation is that in reality substitution is rarely proportional. The Hausman-McFadden and the Small-Hsiao tests allow checking whether the IIA property is violated.

Second, probit models are derived under the assumption that ε_{ij} follows a normal distribution. Third, mixed logit models are based on the assumption that the unobserved portion of utility consists of a part that follows any distribution specified by the researcher ε_{ij} plus a part that is iid extreme value.

The dependent variable assumes discrete values. The simplest form is when the dependent variable is binary. In this case, DCMs will be called binary logit or probit models. When the dependent variable has more than two alternative choices, one refers to multinomial type of DCMs (e.g., multinomial logit or probit models). Depending on the nature of the dependent variable, multinomial models can be ordered (e.g., product categories), nonordered (e.g., transport mode choice), or sequential. Last but not least, Tobit models are variants of DCMs in which the dependent variable is censored. In other words, the variable is observed in only some of the ranges (Maddala 1983).

Distance Contract

► Distance Selling and Doorstep Contracts

Distance Selling and Doorstep Contracts

Sven Hoeppe

Center for Advanced Studies in Law and Economics (CASLE), Ghent University Law School, Ghent, Belgium

Guest Researcher, Max Planck Institute for Research on Collective Goods, Bonn, Germany

Abstract

Distance-selling and off-premises contracts are two major ways in which consumers and sellers interact. Law and economics research has established that these interactions potentially suffer from market power of sellers, from both ex-ante and ex-post information asymmetries, and from consumer bounded rationality. The most promising tool analysed and advocated by law and economics scholars is a cooling-off period coupled with a right of the consumer to withdraw from the contract. This entry surveys law and economics research on these concerns. Interestingly, relevant questions to this line of research remain, which have been brought to attention mainly by insights from behavioral economics. To exemplify and inspire further research along these lines, this entry discusses potentially perverse incentives created by withdrawal rights and the impact of fairness concerns on the consumer choice to withdraw.

Synonyms

Direct selling; terminology in business; Distance contract; Distance selling contract; Doorstep contract; Off-premises contract

Definitions

A **distance selling** contract is a sales contract concluded between a consumer acquiring some good or service and a business partner selling it without the simultaneous physical presence of either the consumer or the professional seller and with exclusive use of one or more means of distance communication until the contract is concluded. Usually the law also requires the professional seller to have employed an organized distance sales mechanism.

A **doorstep contract** is any contract between a consumer acquiring some good or service and a business partner selling it, either:

- (1) Concluded in the simultaneous physical presence of a professional seller and consumer but at a location that is not the business premises of the professional seller or
- (2) Concluded on the business premises of the professional seller (or through any means of distance communication) immediately after the consumer was personally and individually addressed at a location that is not the business premises of the professional seller in the simultaneous physical presence of the professional seller and consumer or
- (3) Concluded during an excursion organized by the professional trader for the purpose or to the effect of promoting and selling the goods or services to the consumer

Introduction

Doctrinal lawyers of consumer law tend to opine that a consumer is in an inferior bargaining position compared to professional seller of a good or service (e.g., Bourgoignie 1992; Weatherill 2005; Loos 2009; Eidenmüller 2011). Is the consumer not less skilled, less knowledgeable, economically much more fragile, and thus equipped with much less bargaining power? The fear that consumers will be exploited if they are not legally protected also resonates in European consumer law (cf. Hoepfner 2012).

This entry surveys, introduces, and reviews law and economics scholarship on two key elements of consumer protection law: distance selling and off-premises – or doorstep – contracts. Law and economics contributions on the topic can be distinguished into two streams. One analyzes the relationship of the contracting parties. The other develops legal responses to specific structures in this relationship. It is clear that the results of the latter depend on insights of the former.

Thus, also the structure of this entry is given. After the economic characteristics of the relationship between consumers and sellers have been introduced, this entry devotes sufficient space to a discussion about the arguably most important tool that is widely used to address the perceived imbalance between consumers and sellers, namely, the right to withdraw from a distance or doorstep contract within a specified amount of time called a “cooling-off period” that, if granted, typically last three full weeks in the USA and two weeks in Europe. Moreover, this entry will also address some concerns about this consumer protection instrument.

The Transaction

Distance selling and doorstep sales have undisputed advantages, mainly a reduction of distribution costs and dissemination of product information across the market, thereby facilitating welfare-increasing transactions. However, these advantages are curbed by specific drawbacks that also result from the nature of distance selling and doorstep transactions (cf. Rekaiti and Van den Bergh 2000; Eidenmüller 2011, Hoepfner 2012).

Information Problems

If the theoretical assumption of complete information of contracting parties may not be satisfied, allocative efficiency is endangered. Therefore, one main problem of distance and doorstep transactions is that consumers are “in the dark” (Dickie 1998, p. 217) regarding both the seller and the quality of the good. The seller may be unreliable or even fraudulent. The good may possess

characteristics that are worse from what the consumer expected.

In other words, there is a multidimensional, *ex ante* information asymmetry between the contracting parties. Without further information – e.g., through inspection of the product – it is very difficult for the buyer to form beliefs about the seller's reliability and product quality. If the product is rich in experience and/or credence (trust) dimensions, even inspection could not ameliorate the information problem because they are (nearly) impossible to observe (Rekaiti and Van den Bergh 2000). *Ex ante* information asymmetries – i.e., hidden characteristics – are especially troublesome for the pre-contractual stage. The economic conjecture is that inferior goods crowd out superior ones through adverse selection. In the limit, only the worst quality goods will remain in the market (Akerlof 1970).

Market Power

Although there are often alternative suppliers or close substitutes readily available for products sold in distance and door-to-door transactions, a specific concern of these transactions is temporary market power. This special twist is caused by so-called situational monopolies (cf. Rekaiti and Van den Bergh 2000, Hoeppepner 2012). "Situational monopolies arise out of particular circumstances surrounding particular exchanges, where this transaction-specific market power is exploited opportunistically" (Trebilcock 1993, p. 101) to extract supracompetitive prices.

How can temporary market power be established although market structure, objectively, is not conducive for concentration? Lele (2007, p. 45) posits that monopolies constitute "an ownable space for a useful period of time." This emphasizes the importance of marketing techniques that temporarily may convince consumers that it will be more costly to engage in alternative search. In door-to-door transactions, crucially important elements are high-pressure sales techniques that lock in the consumer (Hoeppepner 2012). There is a plethora of these techniques. Very familiar to everyone, for instance, may be the buy-on-deadline pattern. This pattern uses the

idea that the consumer will lose out if she does not close the deal right away and is therefore designed to rush the buyer into a decision without proper consideration. It can include anything from first-time-only benefits that accompany the sale, to predictions by the salesperson that the price of the good will drastically increase tomorrow, to the sudden surprise that the good is the last in stock. In regard to distance selling, for example, Rekaiti and Van den Bergh (2000) mention techniques such as an advertisement that claims product uniqueness or vending mechanisms that induce unreflective buying that may induce temporary market power.

Nonrational Behavior

Rekaiti and Van den Bergh (2000) also take issue with the standard assumption of consumer rationality. Consumer preferences may, in contrast to standard economic theory, not be stable over time. To substantiate this idea, the researchers elaborate on possibly inconsistent intertemporal preferences (e.g., Frederick et al. 2002), psychological costs of regret contingencies (cf. Goetz and Scott 1980; Coricelli et al. 2005), and reduced risk perception leading to less deliberative decision-making.

Hoeppepner (2012) delves more deeply into psychological research and the underlying processes that may likely influence consumer decision-making. He adds to the discussion the fact that the ability to predict how the satisfaction of one's decision evolves over time is crucial for decisions to align with the rationality assumptions (cf. Loewenstein and Schkade 1999). It turns out, however, that individual predictions of one's future affect – hence also preferences, decisions, and behavior – are not very accurate. Often these assessments are biased toward initial salient impressions that are more readily available. People who do affective forecasts systematically have it wrong (cf. Gilbert and Wilson 2007). Several sources of error are involved in these predictions. Important for buying decisions in distance and doorstep transactions are the so-called hot/cold empathy gap and the projection bias. Empathy gaps occur when present and future predictions of future affect go hand in hand with different

states of arousal. For instance, a person, who is now excited about a new product and makes a prediction about her future affect concerning the product, is likely to fail to account for satiation effects. Therefore, the person will overestimate the product's impact on his utility. This will result in projection bias: the individual tendency to falsely extrapolate current preferences into the future. This interplay of empathy gap and projection bias often leads to problems of self-control and helps explain impulsive decisions and even self-destructive behavior (cf. e.g., Loewenstein et al. 2003). It is these self-control problems that are worrisome in regard to consumer's decisions about entering a transaction. If the mentioned phenomena undermine utility-maximizing consumer behavior in consumer-seller relationship, this may justify legal intervention (see below).

Remedy: Withdrawal Rights

In response to the specific characteristics of distance selling and doorstep transactions, most jurisdictions have implemented statutory rules that mandate withdrawal rights for the consumer. It allows buyers to inspect the purchased goods and – without any reasons – return the goods to the seller within a certain period of time (cooling-off period), whereas the seller has to reimburse all payments received from the buyer. In the EU, based on the Directive on Consumer Rights (Directive 2011/83/EU of the European Parliament and of the Council of 25 October 2011, OJ 2011 L 304/64), withdrawal rights feature prominently in contract law, especially in distance selling and doorstep transactions (cf. Loos 2009, Eidenmüller 2011).

Unless contractually agreed upon, in the USA, sellers usually do not have an obligation to take back goods that simply do not satisfy consumers. Consumers do not have a generic right to withdraw. Even in the USA, however, withdrawal rights are sometimes provided for certain goods, for instance, by an FTC regulation for door-to-door transactions and by some state statutes for special kinds of distance selling, such as telemarketing (cf. Ben-Shahar and Posner 2011).

As a matter of fact, before mandatory rules were introduced that granted withdrawal rights (cf. Borges and Irlenbusch 2007) or where such rules do still not exist (cf. Ben-Shahar and Posner 2011), a surprisingly large majority of sellers already voluntarily offered, or offer, a return option. This observation leads to different views among law and economics scholars on withdrawal rights. Some do understand the right to withdraw as part of the optimal contract between consumer and seller (Ben-Shahar and Posner 2011). The majority view, however, is that these and similar rights are remedies for potential market failure (e.g., Rekaiti and Van den Bergh 2000; Borges and Irlenbusch 2007; Hoepfner, 2012; Stremitzer 2012) and is, therefore, somewhat close to the traditional legal perspective. This antagonism deserves attention in future law and economics scholarship.

Another interesting piece of information is the extent to which the right to withdraw is exercised. According to questionnaire results reported by Borges and Irlenbusch (2007), return frequency among German mail-order sellers increased from 24.2% in 1998 to 35% in 2004. However, other estimates of the rate of return are much lower (cf. OFT 2004). The different inquiries do not amount to consistent evidence. One has likely to distinguish between the specific kind of transaction and also between different kinds of goods. Drawing conclusions based only on these numbers appears to be inappropriate.

A Cure for Market Failure?

Withdrawal rights in distance selling and doorstep contracts are supposed to restore the balance of interest in consumer-business transactions by protecting consumers. In consideration of the market power of sellers, withdrawal rights render situational monopolies contestable. Potential withdrawal and cooling-off period facilitate access to the consumer by the competition and, thus, market entry. If rational sellers anticipate this, they may be disciplined by the legal rules (Hoepfner 2012). In this sense, legal rules can control market power (Stremitzer 2012).

Withdrawal rights may also counter some problems of nonrational consumer choice where

utility-maximizing choice is endangered. A cooling-off period facilitates risk perception to adjust and may bring attention to the contrast between long-term preferences and short-term choice (Rekaiti and Van den Bergh 2000; Hoepfner 2012). However, before jumping to hasty conclusions about legal intervention on these grounds, one has to carefully demonstrate that such and similar phenomena are indeed at work. Most of the phenomena discussed are context-dependent, and often, the different causes of anomalies are not well understood. In this regard, Korobkin (2003) has written an excellent article on the intricacies and complex problems that the endowment effect poses for legal analysis. Similar complexities also need to be considered in regard to consumer-seller relations. Affective forecasting errors are both persistent and prevalent (see above). This poses a problem only, however, if the mismatch between *ex ante* projection about utility and actual long-term satisfaction indeed causes an over-investment. More recent research revealed that adaptation processes are very different between simple, material consumption goods and experiential purchases. Specifically, after an initial rush of utility – that biases affective forecasting – people adapt to the consumption of material goods rather fast. By contrast, the people adapt to experiential purchases rather slowly, and sometimes their satisfaction even grows (Van Boven and Gilovich 2003; Frank 2008, Chap. 8; Nicolao et al. 2009). Therefore, the one-size-fits-all solution of withdrawal rights may be drawn into question at least insofar as disadvantageous consumer decision-making in regard to projection bias is concerned. The relation between the different aspects of nonrational consumer decision-making and possible legal interventions, however, is left to detailed future research. Moreover, Korobkin (2003) warns that once legal scholars import into their work concepts and findings from other disciplines, the sophistication of translating these findings into policy-relevant analyses differs a lot.

Therefore, one should require a higher burden of proof to justify legal intervention on these and similar grounds, which are foreign to the legal scholarship. In fact, this concern emphasizes the

importance of more carefully testing implications and policy solutions – possibly in the laboratory (cf. Engel 2013) – before implementing them in practice. Such testing also has the potential to reveal unanticipated forces at work (see below).

Withdrawal rights also seem to be an appropriate remedy for the multidimensional, *ex ante* information asymmetry. In fact, this has been suggested to be “the most fundamental aspect of building consumer confidence” (Dickie 1998, p. 223). On the one hand, withdrawal rights and cooling-off periods enable a discovery process for testing mainly experience dimensions of a product, but also other product characteristics that could not be validated *ex ante*. Therefore, withdrawal rights can be understood as information technology (cf. Hoepfner 2012).

On the other hand, however, it is also noteworthy that mandatory withdrawal rights delete important information signals. Signaling credible commitment is not possible under a mandatory regime for those sellers that are reliable and offer high-quality products and want to distinguish themselves from their inferior competitors. The information signal of voluntarily offering a withdrawal right gets lost (cf. Hoepfner 2012). As is the case with warranties (cf. Emons 1989), the incentive function remains insofar as better quality products, and higher seller reliability leads to lower withdrawal costs (Rekaiti and Van den Bergh 2000).

Moreover, although a withdrawal right may ameliorate the *ex ante* information problem, this mechanism also introduces *ex post* information asymmetries (hidden action). The danger of *ex post* opportunism, specifically consumer moral hazard, looms large (Stremitzler 2012). The consumer may, e.g., use the product to an excessive degree and just ship it back after making use of his withdrawal right. To align post-contractual incentives, distance and door-to-door selling regimes often implement liability rules for the consumer in case of excessive or even normal usage of the good that causes deterioration of the good.

Finally, the potential to unilaterally exercise a withdrawal right burdens sellers with additional risk. This risk leads to relatively increased costs for the seller because only a share of transactions

is completed. This translates to higher prices (Rekaiti and Van den Bergh 2000; Hoepfner 2012).

To conclude, it appears that there is an efficiency rationale to justify withdrawal rights. Ben-Shahar and Posner (2011) argue – on the basis of their model – that there is reason to recognize a generic right to withdraw but that the rule should be a default rule, not a mandatory rule. However, their model hinges on information asymmetries and the perverse ex post consumer incentives. The other aspects discussed here do not enter. Therefore, the potential of withdrawal rights to address causes of market failure is not so clear-cut after all. At best, they are second-best solutions (critically toward withdrawal rights also: Eidenmüller 2011; Hoepfner 2012). Moreover, there is more room for future research than one may think. The following passages exemplify that relevant research on withdrawal rights is far from exhausted.

Perverse Incentives?

If one wants to draw a conclusion so far, it will likely be that withdrawal rights can lead to efficient incentives ex ante and ex post as long as the right is implemented correctly. In fact, a consumer right to withdraw coupled with the obligation to pay depreciation costs is analytically comparable to breach of contract when coupled with reliance damages (Ben-Shahar and Posner 2011).

One unintended consequence of such a simple way to terminate the contract has been brought to attention by Hoepfner (2012). He emphasizes that consumers face two decisions: (1) to contract for the good and (2), if contracted, to withdraw from the contract. In light of the second decision, which can be compared to an opt-out opportunity (not withdrawing is the default), sellers have an incentive to increase consumer compliance with the contract. In other words, sellers have an incentive to manipulate downward the probability that consumers withdraw from the contract. This would put a question mark behind the presumed effectiveness of withdrawal rights.

In the context of doorstep sales, Hoepfner (2012) further elaborates that sellers can use specific bargaining techniques that exploit behavioral

quirks that relate to the two important driving forces in individual decision-making: reciprocity and consistency. These mechanisms, however, can be easily translated to distance selling. Once the withdrawal stage is reached, consumers may face a status quo dilemma. In light of economic (e.g., transaction cost, uncertainty, specific investments, switching cost) and psychological variables (e.g., risk aversion, loss aversion, regret aversion), consumers may disproportionately often decide for the status quo. They may not withdraw although withdrawal would be the optimal choice.

Hoepfner (2012) suggests that, if these mechanisms work out as in his analysis, there will be an inefficiently high number of contracts entered into and an inefficiently low number of withdrawals. Consequently, as a first step he suggests changing the default from the withdrawal option from presumed consent to presumed denial – from opt out to opt in. However, these conclusions should be properly tested before jumping to policy conclusions by making use of empirical methods.

Fairness Considerations?

As mentioned above, withdrawal rights are thought of as a mechanism to restore the balance of interest, or to promote fairness, where individual skills, information, and/or bargaining power are very unequally distributed between contracting parties. The idea of fairness is one of the most important normative ideals in legal scholarship (cf. Kaplow and Shavell 1999; Singer 2008). In many contexts, the law requires contracting parties to take into account the legitimate interests of the other parties. Since research in behavioral economics has gained momentum, fairness considerations in exchange relationships also feature prominently in economics and law and economics (e.g., Kahneman et al. 1986; Konow 2003).

However, whereas withdrawal rights are supposed to promote fairness in an imbalanced relationship, they also provide the opportunity for the entitled parties to exploit their legal position. Borges and Irlenbusch (2007) experimentally tested the effect of withdrawal rights in the context of distance selling transactions. The researchers are

investigating two aspects. First, they test whether the exclusive liability of the seller for the return costs increases the withdrawal rate as compared to a situation where return costs are shared. The intuition is that, given no return cost, opportunistic buyers have an incentive to either order the good and reap the short-term value of use or order multiple goods with uncertain characteristics and afterward – through the withdrawal right – return the unfit goods to the seller for a reimbursement of the purchase price. Second, the researchers test whether the shift from a voluntarily granted withdrawal right to a statutorily mandated right increases the withdrawal rate. This prediction is based on fairness considerations. Briefly put, there is substantial evidence that people reciprocate perceived fairness cues (e.g., Fehr and Gächter 2000; Falk and Fischbacher 2006). If a seller voluntarily offers a withdrawal right, sellers may perceive this as fairness-induced kindness and reciprocate by exercising their withdrawal right less opportunistically. However, legally imposing a right to withdraw may provide an entitlement to the buyer to exercise this right and, moreover, signal that sellers are legally presumed not trustworthy. Mandating a right to withdraw may render buyers less fairness oriented. The researchers manipulate these variables across different distance selling scenarios.

The results indicate, first, that jointly bearing the return cost does not significantly change buyers' decision-making; in general, buyers do not behave friendlier, i.e., less opportunistically, if this does not also maximize their own payoff. Put differently, the mere existence of return costs does not distract participants in the laboratory to misuse their withdrawal right.

Moreover, although individual payoff maximization appears to be a central driver of buyers' behavior observed in the lab, Borges and Irlenbusch (2007) find clear indication that fairness considerations also play a systematic role in general. More interestingly, the researchers find an observable difference in how buyers interact with sellers depending on whether the withdrawal option was voluntarily provided or mandated. The number of choices that are unfavorable for the seller is significantly higher when the withdrawal

right is legally provided. In fact, from the experimental data, it is estimated that an unfriendly choice is 7.4% more likely under a mandatory regime (Borges and Irlenbusch 2007, p. 97). Ironically, implementing a statutory withdrawal right to protect buyers from unfair behavior crowds out their fairness considerations. This is clearly of concern for consumer contract law.

Summary

This entry quickly surveyed law and economics research important to analyze the consumer-seller relationship. An understanding of this relationship is fundamental for distance and door-to-door contracts, specifically, and consumer contract/protection law, in general. On this basis, the entry offers a discussion on research in law and economics about the major remedy available to consumers in these relationships, namely, withdrawal rights.

A provisional result of law and economics research is that withdrawal rights are able to address the imbalance in situational market power of sellers, ex ante information asymmetries that threaten the lemon market process, and non-rational consumer choice. However, withdrawal rights are second-best solutions only since they merely shift risk from consumers to sellers and facilitate consumer ex post opportunism. At least, withdrawal rights ought to be coupled with an obligation of the consumer to pay depreciation costs. This is analytically comparable to breach of contract coupled with a liability for reliance cost that is well known from seminal law and economics research. This solution is more suitable to establish efficient incentives.

However, despite this efficiency rationale research on distance and doorstep contracts is far from conclusive. Some information signals inevitably get lost in a mandatory regime. Although defaults tend to be sticky, a default rule on withdrawal rights may lead to efficiency gains compared to a one-size-fits-all solution because it facilitates sorting and signaling of heterogeneous buyers and sellers. Moreover, more research is needed concerning the perverse incentives to manipulate downward the withdrawal rate and

concerning the dynamics between the voluntary and the mandatory provision of withdrawal rights as well as the interplay with social norms and preferences.

Definition

Double tax conventions are international treaties between sovereign states to assign taxing rights between them in order to avoid double taxation. They tend to follow model conventions, the most prominent being the OECD Model Convention. Double tax conventions based on the OECD Model Convention consist of seven chapters. Chapter 1 regulates the scope. Chapter 2 contains the rules of interpretation and the definitions. Chapters 3 and 4 include the rules on the allocation of taxing powers. Chapter 5 provides the two methods for relieving international double taxation. Chapter 6 addresses special provisions and chapter 7 the final provisions. After introducing the concept of international double taxation, this entry defines double tax conventions and argues why countries might wish to sign such a treaty, and why not. The last chapter before the conclusion discusses special issues with double tax conventions, in particular its effect on profit shifting and foreign direct investment.

Introduction

The exclusive right to levy taxes is a defining principle of the public sector. As long as we remain firmly within the limits of the nation state (Bodin 1579), this principle remains largely uncontested (McLure 2001). Once we leave these narrow confines, the issue at hand gets more difficult. Every single nation state may be inclined to impose taxes elsewhere, however small the link is. Without a supranational authority, nation states will dispute over the tax base. This is the dilemma of international taxation, which double tax conventions (DTC henceforth) aim to overcome. There are over 3.000 DTCs worldwide (of about 17.000 potential treaties if every country in the world would have a treaty with every other country) (IBFD 2017). A major project for their coordination is undergoing through the so-called multilateral instrument, which is in essence an international legal instrument that steers bilateral treaties towards cross-border consistency at the worldwide level without requiring the renegotiation of such treaties.

This contribution will answer the following questions:

- What are double tax conventions?
- Why do countries form DTCs? (And related, why do countries decide not to form a DTC? And why might countries terminate DTCs?)
- Finally, what are the consequences of DTCs?

We will answer these questions as follows. In the following entry, we will present the problem of double taxation, which is the historically dominant argument for DTCs. Next, we will define DTCs and explain their main elements and historical evolution. Thereafter, we will discuss several issues within DTCs, before discussing international tax coordination as a potential solution.

International Double Taxation

International double taxation arises when two governments claim taxing rights on the same revenue or wealth in respect of the same taxable year.

Depending on whether it affects the same taxpayer in a legal or economic sense, it can be characterized as juridical or economic double taxation. Tax law literature differentiates between juridical and economic double taxation, according to whether the duplication of the tax burden affects one and the same individual or entity (juridical double taxation) or two different ones (economic double taxation).

In principle, the absolute nature of tax sovereignty could lead any government to claim unilaterally complete worldwide taxing rights on everything. However, in practice this does not happen, since national tax sovereignty finds limits in the exercise of taxing powers at the international level. Therefore, the concept of tax jurisdiction is narrowed down to the situations in which a country can establish a reasonable genuine link, based on the so-called connecting factors, with its right to exercise tax sovereignty.

International double taxation is the result of the exercise in parallel of more than one tax jurisdiction and can arise as a consequence of similar or different connecting factors. The connecting factors to tax jurisdiction are essentially of two types, namely personal and objective. In the case of income taxation, objective connecting factors tax income as such, i.e., for the mere fact of being sourced on the territory on which the state exercises its jurisdiction. The state that exercises its taxing jurisdiction on a territorial basis through objective connecting factors is often referred to as the state of source. Because of the objective connection with the taxing jurisdiction, such state does not take into account any personal circumstance of the taxpayer who derives this income.

Personal connecting factors have developed more recently in the twentieth century for allowing one state to exercise its taxing jurisdiction on the overall ability to pay of a taxpayer, even when s/he derived income outside the territory of the state. For this reason, it was originally called extraterritorial taxation. In fact, it is not, since personal connecting factors allow countries to exercise their jurisdiction on the taxpayers established on their territory. The need for a factual link with the territory of a country has steered the development of personal connecting factors in

line with criteria that expressed a sufficient presence of the taxpayer on such territory. For this reason, most countries have adopted residence or domicile to establish the personal link with their tax jurisdiction. Therefore, a country exercising its tax jurisdiction based on a personal connecting factor is often described as the country of residence (Connecting factors may vary whether we are discussing natural or legal persons.). However, some countries, most notably the United States, adopt citizenship as its main personal connecting factor, thus allowing a more direct link with the public services that it provides to persons holding this status.

Countries have stretched both types of connecting factors over the years, with a view to extending their tax jurisdiction and preventing possible attempts to circumvent it. Accordingly, legal fictions have deemed income to be within the national territory for source-based taxation purposes and the number of personal connecting factors has increased in order to exercise residence-based taxation in the presence of any minimum personal link with the tax jurisdiction.

The need to counter tax avoidance and evasion has brought personal connecting factors to operate in a country even when a taxpayer with separate legal personality is established on the territory of another country and is controlled by a resident person of the former country, such as in the case of controlled-foreign-company (or CFC) legislation (OECD 2015). From the perspective of the country of source, the stretching of objective connecting factors was caused by the need for countering base erosion of value created on the territory and shifted to that of another tax jurisdiction. Accordingly, measures like the diverted profits tax in Australia and the UK (Nguyen 2017), and the Indian equalization tax on services (Lahiri et al. 2017) have been introduced in order to safeguard the exercise of taxing powers on income sourced within the national territory.

This situation broadens the potential for the exercise in parallel of tax jurisdiction and magnifies the exposure of cross-border situations to international double taxation, which can arise in three main groups of conflicts of tax jurisdictions.

The most frequent and typical case of international double taxation is the one caused by residence-source conflicts. This occurs for instance when income is generated in one country (source) and the benefit accrues to a resident in a different country. However, international double taxation can also be the outcome of residence-residence conflicts (or similar phenomena involving a conflict with another personal connecting factor, such as citizenship) and of source-source conflicts.

With few exceptions, taxation exhibits negative welfare implications due to its distortionary effect on prices. Double taxation even more so. Consider the simple case of a 2 country, 2 goods world, where for the sake of simplicity supply is infinitely elastic (standardized at $p = 1$) and linear demand is given by $q = k - p$. Both markets create total welfare of k^2 . The introduction of a tax t on one market reduces welfare by half the square of the tax rate, $t^2/2$. Now suppose country 1 taxes market 1 at a tax rate t , and country 2 taxes market 2 coincidentally at the same rate. The global deadweight loss of taxation would be t^2 . If instead both countries insist on taxing the same market, the deadweight loss on this market would amount to $(2t)^2/2 = 2t^2$. Even if neither country touches the other market (double nontaxation), the deadweight loss of double taxation exceeds by a large margin single taxation. Government revenues, too, suffer from double taxation. In the case of single taxation on both markets, global governments revenues amount to $2t(1 - t)$, whereas in the case of double taxation on a single market, global tax revenues would equal $2t(1 - 2t)$, which is less than the above due to the distortionary effect of taxes (Nowotny and Zagler 2009, 286 ff).

In principle, there is no natural order of priority when two states exercise in parallel their taxing jurisdiction. Historically, it has even occurred that more than 100% of the tax base has been taxed due to double taxation (Herndon 1932). For this reason, the introduction of specific legal remedies is needed in order to counter international double taxation.

One simple remedy to international double taxation is obviously unilateral measures. Each

of the two countries in the above example can unilaterally forgo the right to tax a particular market, thus avoiding double taxation. While unilateral measures may help to avoid double taxation, they may generate unwanted side effects in cross-border activities. Forgoing taxing rights will put domestic exporters on par with their foreign competition (export neutrality), but it will at the same time treat differently foreign importers, who will not need to pay taxes in the source state as opposed to their domestic competition (import non neutrality) (Lockwood 2001).

Another remedy is to address international double taxation of income by means of bi- and multilateral measures framed into international tax treaties, specifically designed to counter this phenomenon. Those treaties, which we shall from now on indicate as double tax conventions, essentially coordinate the exercise of taxing powers with a view to preventing, reducing, and relieving international double taxation.

Double tax conventions are most frequently bilateral and drafted along a common international pattern, based on different model conventions, most notably the OECD Model Convention. Besides the OECD Model, other important model conventions are the UN model and several national models, such as the US model. They regulate the exercise of tax jurisdiction on cross-border situations by establishing additional conditions to either Contracting State. In some cases, they attribute exclusive taxing powers, thus preventing international double taxation. In other cases, they keep the right of each Contracting State to exercise its taxing jurisdiction, sometimes establishing limits for either of them (such as in the case of passive income, which the source state can tax only up to the maximum amount agreed in the treaty), and provide for common rules that relieve international double taxation.

Treaty measures for relieving international double taxation are essentially similar to the ones that may apply based on domestic law. Credit and exemption are the two main methods for relieving international double taxation in the state of residence of the taxpayer. However, their effects are different from a legal (CJEU, FII Group Litigation I 2006, paras. 45–48, FII Group

Litigation II 2012) and economic perspective. For this reason, in principle one State may not apply different methods to relieve (economic) double taxation in purely domestic and cross-border situations.

When credit applies, the state of residence exercises its taxing jurisdiction on a worldwide basis, thus also on foreign sourced income or wealth, and allows for a deduction of taxes paid in the other state. This mechanism turns lower foreign taxes paid in the state of source into a lower deduction against taxes due in the residence state, thus pursuing capital export neutrality. However, this mechanism operates in a way that may not affect the right of the latter country to exercise its taxing jurisdiction on domestic sourced income or wealth. This limitation, also known as ordinary credit, gives no relief for foreign taxes when higher than those applicable in the residence state.

When exemption applies, the state of residence does not exercise its taxing jurisdiction on foreign-sourced income and wealth, thus turning foreign taxes into final and allowing taxpayer to bear the same tax burden of residents of the source state. This method pursues capital import neutrality and approximates the exercise of taxing jurisdiction to what it would normally be in a pure territorial system. However, it makes the exercise of taxing powers in cross-border situations vulnerable to phenomena of double nontaxation, which occurs when the source state does not tax income or wealth that it would be entitled to under the double tax convention. For this reason, double tax conventions generally allow for a switchover to credit in such circumstances.

A variation of the exemption method – known as exemption with progression – preserves tax progression, in order to allow domestic-sourced income of individuals to be taxed at the rate that would correspond if all income had been sourced in the state of residence.

A variation of the credit method – known as tax sparing – where the residence State is bound to give credit for the taxes that should have been paid in the source State, whether the source State chooses to exercise taxing rights or not; therefore, allows the source State to pass on the benefits of

any incentives to the taxpayer. This preserves the right of the source state to pursue its international tax policy goals without interferences by the residence state. This method may also be used for allowing the source state to keep the effects of its tax incentives at the international level (Brooks 2009).

Although remedies against international double taxation can also operate under domestic law, their functioning at treaty level provides qualitatively better results, since the latter may coordinate the exercise of taxing powers between the Contracting States and reduce the extent to which international double taxation may arise. This is one of the reasons for double tax conventions to become so common at the international level.

Double Tax Conventions (Why Countries Conclude or Not a DTC)

The Worldwide Network of Bilateral Double Tax Conventions

The first modern double tax convention goes back to 1899 when Prussia and Austria-Hungary signed such a treaty (Easson 2000). Since then, the number of treaties has been rising steadily; at the beginning, mostly industrialized countries entered into such treaties with each other. During the last two decades, developing economies have increasingly been integrated into the global treaty network. After 1990, the number of DTT signatures has been surging, so that around 60% of today's DTTs have been signed in the last 20 years (Baker 2014).

The historical development of double tax conventions is the outcome of the activism of international organizations. Their technical work in this field started with the economic studies on international taxation carried out under the auspices of the League of Nations (LoN) from the 1920s onwards and continued with the proposals and drafts of the Organization for European Economic Cooperation (OEEC) in the 1950s. Since the preliminary studies, it became clear that the establishment of a global multilateral framework was a too ambitious goal to achieve, due to the numerous differences across the various

countries' tax systems. For this reason, double tax conventions have essentially developed along the paths of bilateral negotiations.

However, the current international framework for double tax conventions presents a significant degree of coordination across bilateral treaties, which is largely the outcome of the constant efforts by the Organization for Economic Cooperation and Development. The Model Tax Conventions released by the OECD since 1963 have come to constitute the main reference for the clauses contained in most of the existing bilateral tax treaties around the world. The OECD Model pursues tax policy goals of capital exporting countries in the allocation of taxing powers. It owes its success to the very high standards of consistency in promoting this standard and to its Commentaries, which extensively elaborate on the interpretation of clauses of double tax conventions. For this reason, it quickly turned into the main source for negotiating treaties between OECD countries.

Since 1980, there is also a UN Model Convention. The main goal pursued by this Model Convention is to provide for allocation rules that better pursue the international tax policy goals of developing countries. However, the diffusion of this UN Model Convention in related tax treaties has been rather limited in relations between developed and developing countries and, more recently, also in treaties between developing countries.

The Policy Goals of the OECD Model Convention and Its Diffusion in Relations with Developing Countries

The diffusion of the OECD Model (OECD 2017) in double tax conventions with – and, sometimes even between – developing countries is a potential source of concern, since this model reflects the policy goals of capital exporting countries and developing countries have not contributed to develop its clauses. Yet, such countries agree to sign double tax conventions shaped along the OECD Model. The existence of asymmetries in flows of income and capital with capital exporting countries turns the conclusion of double tax conventions for such countries to cause more losses in their exercise of taxing powers than advantages.

Yet, such countries sign double tax conventions, sometimes for reasons connected with the perception of investors, some other times as a package deal with the signature of other international treaties or for other reasons.

Industrialized (typically capital exporters) and developing countries (typically capital importers) may indeed have different motives when signing a DTC. Fostering outbound investment and thus encouraging the international expansion of domestic companies may arguably be more relevant for capital-exporting countries. For capital importers, encouraging inbound investment may be more in the focus, with policy makers wishing to attract foreign direct investment entailing the transfer of skills and technologies and thus fostering economic growth (Lang and Owens 2014). Finally, the function of DTCs as a signaling device indicating that the signatory states play by the internationally accepted tax standards may be more relevant for developing countries (Dagan 2000).

The Structure of Double Tax Conventions Following the OECD Model Convention

Since most bilateral treaties in fact follow the OECD Model Convention, it makes sense to outline their structure by referring to such Model and its clauses. However, we shall include some reference to the Model Convention drafted by the United Nations when the clauses contained in such Model contains some significant deviations from the pattern provided by the OECD Model. For the purpose of simplicity, we shall focus our analysis of international double taxation by referring to the OECD Model Tax Convention on income and capital. Yet, the OECD has also produced in 1982 a Model Tax Convention on Inheritance and Gift Taxes.

Double tax conventions based on the OECD Model Convention consist of seven chapters. Chapter 1 regulates the scope. Chapter 2 contains the rules of interpretation and the definitions. Chapters 3 and 4 include the rules on the allocation of taxing powers. Chapter 5 provides with the two methods for relieving international double taxation. Chapter 6 addresses special provisions and chapter 7 the final provisions.

The application of the core part of double tax conventions follows in substance four main steps, to which we shall now briefly refer, followed by some brief reference to the special and final provisions. The first step is the entitlement to treaty benefits, also known as the subjective scope of tax treaties. It covers cross-border situations involving persons who are resident of either or both Contracting States. This clause is contained in Article 1, but the concept of residence is to be interpreted in the light of Article 4, which primarily relies on domestic law of the Contracting States, but also includes tie-breaker rules to address cases of dual residence and the residence-residence conflict connected thereto.

The second step is the objective scope of tax treaties, which includes the existing taxes specifically indicated by the Contracting States and the ones that may replace them with similar features. This clause is contained in Article 2.

The third step is the most important one. It contains the 16 clauses that limit the exercise of taxing powers on cross-border income and the one clause on capital covered by the double tax convention. Such clauses are better known as allocation rules and are included in Articles 6–22 (excluding Article 9).

The ones on income essentially regulate six basic types of income (from immovable property, business income, passive income, capital gains, income from employment, and the residual category of other income).

Allocation rules include specific provisions whenever the specific features of income require so in order to achieve a balanced allocation of taxing powers. This can be the case of Article 16 on directors' fees, or of Article 18 on pensions from past private employment, in respect of which the basic rule of Article 15 cannot operate due to the uncertain determination of an actual place of exercise of the activity or its absence. In case no specific allocation rules are deemed applicable, treaties contain general rules as a fallback option.

The existence of different limits to the exercise of taxing powers across the allocation rules can be the unintended source of cross-border tax biases and gives rise to a potential for tax avoidance. For instance, the clauses on passive income in the

OECD Model Convention may allow for higher withholding taxes on dividend than on interest. Furthermore, the OECD Model Convention prevents double taxation on royalties and capital gains by allocating exclusive taxing powers to the state of residence. This context may induce taxpayers to alter their behavior and prefer capitalization over distribution of dividends. However, it may also create a potential for circumvention of the clauses in order to obtain unintended savings of taxes in the state of source through rule shopping (which is a form of tax avoidance), such as for instance, when taxpayers seek characterization as interest over that as dividends.

From the perspective of the allocation of taxing powers, we can group the main bulk of double tax convention clauses into three categories. The first category includes clauses that allocate taxing powers to one Contracting State and thus prevent international double taxation, thus making the fourth step unnecessary. Such clauses are the ones contained in Articles 7 (in the absence of a permanent establishment), 8, 12, 13 (3), 13 (5), 15 (1) (first sentence), 15 (2) (if the three negative conditions are not met), 18, 19 (1) (a), 19 (1) (b), 19 (2) (a), 19 (2) (b), 21 (1), 22 (3), 22 (4). Furthermore, this is also the case of Article 14 of the UN Model Convention in the absence of a fixed base. Interestingly, most clauses of this variety allocate taxing rights to the resident state, except where shipping, aircraft, etc. are covered. However, there is a proposal to change these provisions to favor residence taxation as well in the 2017 update of the OECD Model Convention.

The second category includes clauses that allocate taxing powers to both Contracting States but limit the exercise of powers by the Contracting State of Source up to a maximum amount. When the State of Residence relieves double taxation by the credit method, this approach reduces the risk of unrelieved international double taxation. Such clauses are the ones contained in Articles 10 (2), 11 (2) and, in the UN Model Convention, also Article 12 (2). The third category includes clauses that allow both Contracting States to exercise their taxing powers, thus leaving it up to the State of Residence to relieve double taxation. Such clauses

are contained in Articles 6, 7 (for income attributable to a permanent establishment), 10 (1), 10 (4), 11(1), 11 (4), 12 (when the beneficial ownership requirement is not met), 12 (4), 13 (1), 13(2), 13 (4), 15 (1) (second sentence), 15 (2) (when the three negative conditions are met), 16, 17, 21 (2), 22 (1) and 22 (2), as well as, Article 14 (in the presence of a fixed base), 18 (2) (alternative B) and 21 (3) of the UN Model Convention.

For clauses on allocation of taxing powers falling under the second and third category, the fourth step is necessary. In particular, it obliges the State of Residence to give relief for international double taxation by means of exemption (Article 23A) or credit (Article 23B).

The special provisions apply also beyond the scope of double tax conventions and can be grouped into two main clusters. First, the non-discrimination clauses, contained in Article 24, essentially regulate how the Contracting States may exercise their taxing powers in respect of non-nationals. Second, three provisions regulate the relations between tax authorities of the Contracting States. In particular, Article 25 allows them to interact in order to achieve a common view on the interpretation and application of the convention in the framework of the so-called mutual agreement procedures. Furthermore, Article 26 sets the conditions for mutual assistance concerning cross-border exchange of information in tax matters and Article 27 – not always included in bilateral double tax conventions – the ones related to assistance in the collection of taxes.

The final provisions reiterate the immunities established by international law conventions for members of diplomatic and consular missions (Article 28), define the territorial scope (Article 29), entry into force (Article 30), and termination of the double tax convention (Article 31). Furthermore, the 2017 Draft Update to the OECD Model Convention includes a new treaty clause that limits the benefits of the tax convention in order to counter cases of tax avoidance that may harm the taxing rights of the State of Source. Once approved, this clause will be inserted in Article 29 and will thus imply the renumbering of the last three Articles currently included in the OECD Model Convention.

Although double tax conventions have a bilateral nature and only binding their signatory states, their structure and content are now undergoing an unprecedented process of multilateralization in connection with the implementation of the multilateral instrument that 68 countries have signed on 7 June 2017 in the framework of activities connected with the base erosion and profit shifting (BEPS) project. Essentially, the multilateral instrument constitutes a convention that co-exists with bilateral agreements of the signatory States and steers them towards the agreed goals and minimum standards of the BEPS project, which include the countering of abuse of double tax convention and of harmful tax competition and the solution of cross-border tax disputes.

Why Do Countries Sign DTCs?

The preamble to a DTC is not fixed under the OECD Model Convention and most DTCs contain wording stating that the DTCs have been entered into to prevent double taxation in a cross-border transaction between the two concerned States. However, some DTCs also expressly provide for other reasons such as the “encouragement of mutual trade and investment”. See for example, the preamble and title to the India-Mauritius DTC (1983). The Multilateral Convention to Implement Tax Treaty Related Measures to Prevent BEPS also allows the option to add such language to the preamble.

Over the years, DTCs have come to pursue additional goals to the one of countering double taxation. DTCs may provide certainty in tax matters for international investors, prevent tax discrimination for investments in the other state, and avoid double taxation of income arising in cross-border transactions (Pickering 2013). In particular, DTCs serve to mitigate international tax avoidance and evasion and to protect the domestic tax base. This justifies the conclusion of double tax treaties also with countries that either have lower levels of taxation, or no taxation such as the United Arab Emirates or Hong Kong.

In various ways, DTCs can contribute to achieve these goals. They address cross-border transactions between associated enterprises

(Article 9 of the OECD Model Tax Convention on Income and on Capital (OECD Model)) and they provide for information-sharing between the contracting states (Article 26 of the OECD Model). Furthermore, specific provisions and concepts are inserted such as the limitation of benefits provisions or the beneficial ownership concept, which “restrict access to treaty benefits to residents of the contracting states” (Baker 2014). Accordingly, the Multilateral Convention to Implement Tax Treaty Related Measures to Prevent BEPS (2017) seeks to modify the preamble of covered DTCs to expressly provide that while DTCs intend to avoid double taxation, they should not be used to facilitate double non-taxation or treaty shopping, as a “minimum standard” measure under the BEPS project.

Voget and Lighthart (2011) empirically study the motives to conclude DTCs for a large country sample covering both industrialized and developing countries. They conclude that countries sign DTCs primarily to reduce international double taxation. DTCs mitigate double taxation by “harmonizing tax definitions, defining taxable bases, assigning taxation jurisdictions, and indicating the mechanisms to be used to remove double taxation when it arises” (Baker 2014). Yet, many authors argue that double taxation can be – and by most countries is – prevented unilaterally (Braun and Fuentes 2014; Rixen and Schwarz 2009).

In light of the above, some researchers argue that the main benefit role of DTCs lies in the harmonization and the lowering of withholding tax rates on international capital income (Davies 2003). OECD countries are encouraged to conclude a double tax convention for limiting the exercise of taxing powers by the source state. Reciprocity in flows of income and capital is expected to level out any potential loss of taxing powers between such states.

Whereas reduced source taxation may improve investment attractiveness, this depends on the method used for the avoidance of double taxation. Specifically, the exemption method will typically allow the investor to gain benefits from the lower withholding taxes. However, under the credit method, the lowering of withholding tax rates may also entail “distributional implications.”

Unless tax sparing is provided for, the reduced source taxation results in higher residence taxation, and therefore providing no benefits to the investor. In particular, with asymmetric investment positions, the lowering of withholding tax rates in treaties using the ordinary credit method “involves a revenue transfer from the net capital importer to the net capital exporter” (Rixen and Schwarz 2009). Therefore, the benefits of DTCs are sometimes being described as more on the side of capital exporters (Dougherty 1978).

Chisik and Davies (2004) discuss these distributional implications in the framework of tax-treaty bargaining. Based on a theoretical model, they predict that it may be more difficult for highly asymmetric countries to negotiate a tax treaty. They then show that highly asymmetric countries tend to conclude tax treaties with higher withholding tax rates.

Despite different preferences, having more economical strength and more bargaining power, capital exporters may have the power to pressure capital importers to enter into treaty negotiations (Pickering 2013). Nevertheless, Paolini et al. (2016) point out that DTCs may be perceived by capital-importing countries as means to partly regain their sovereignty with respect to the taxation of income, which non-residents generate on their territories. Due to the treaty, the allocation of taxing rights will be stated clearly and the taxes for business income paid in the capital-importing country will become final and thus relevant for firms. As a result, capital-importing countries will be in a position to use tax policy instruments in order to attract international investment flows.

The above discussion shows the complexity of the treaty formation process. Numerous empirical studies investigate the main drivers behind this process. Generally, we observe that countries have tax conventions in place with countries with which they have close economic ties. Egger et al. (2006) find that the bilateral country size and host government expenditure as a percentage of GDP significantly increase the likelihood that a country-pair signs a DTC. Lejour (2014) finds that sharing a common colonial past and the same language have a significantly positive impact on the probability of two countries concluding a

DTC, while distance is found to have a significantly negative effect. Finally, Barthel and Neumayer (2012) analyze DTC formation patterns focusing on spatial dependence. They find evidence that country-pairs are more likely to sign a DTC the more DTCs have previously been concluded in the region.

Issues with DTCs

DTCs and FDI

DTCs cover a large majority of foreign direct investment (Radaelli 1997). Several studies have examined whether and to what extent FDI responds to different tax treatment, finding that firms do indeed respond to a variety of tax policies and that this can result in an inefficient allocation of investment across countries. This can allocate investment away from its most productive use. One potential method of eliminating this inefficiency is a double tax convention. These treaties adjust the tax environment for investment between treaty partners by specifying the applicable tax base, the withholding taxes that can be applied, and other measures affecting the taxation of FDI.

Double taxation occurs if a multinational company (henceforth MNC) pays tax on the same corporate income earned from economic activity in a foreign country twice: once to the tax authorities of the foreign country, which is host to the economic activity, and once to the tax authorities of the home country, in which the company is domiciled. Double taxation could represent an obstacle or barrier to foreign investment, thus distorting the efficient allocation of scarce financial resources across countries of the world. Yet, DTCs can also reduce FDI in as much as they reduce tax avoidance, tax evasion and other more or less legal tax-saving strategies such as transfer pricing by multinational companies (Blonigen and Davies 2002).

DTCs can increase FDI as they standardize tax definitions and jurisdictions. Janeba (1996) theoretically shows that such coordination can reduce the double taxation of affiliate income. Tax

treaties affect the taxation of multinational enterprises by lowering withholding taxes and increasing tax certainty. In particular, Edmiston et al. (2003) find that uncertainty over tax policy is a significant barrier to FDI. Thus, if a tax treaty reduces the likelihood of a host nation unilaterally changing its tax policy, this added certainty would increase FDI. The combination of these two roles of treaties increases the expected value of after-tax returns from FDI. By contrast, the increased enforcement of transfer pricing regulation may actually exhibit a negative impact on FDI. DTCs can impact FDI also through transfer pricing enforcement regulations. Blonigen et al. (2014) argues that DTCs have a positive effect on FDI, which is larger for firms that use differentiated inputs. These (multinational) firms benefit from treaty provisions establishing guidelines for resolving disputes between taxation authorities. In contrast, firms that use more homogenous inputs are on average less likely to see any significant effect. This difference can be attributed to the additional regulations on the calculation of internal prices and encouraging the exchange of information between authorities. The establishment of anti-treaty shopping provisions inhibits the ability to direct profits through low-tax treaty partners in order to minimize tax payments. Since these increase the taxation of affiliate income in a given host, they would lead one to anticipate that a tax treaty might reduce FDI.

The empirical literature generally finds little evidence for the impact of DTCs on FDI (Louie and Rousslang 2008; Millimet and Kumas 2017). This result is often interpreted suggesting that the FDI increasing aspects of treaties, such as tax certainty or withholding tax reductions are balanced with negative effects as mentioned above, yielding a zero net effect of treaties on multinational enterprises.

Blonigen and Davies (2002) represent the first attempt to estimate the impact of DTCs on FDI. Respectively using panel data on OECD FDI (where FDI is measured as stocks) and US FDI (where FDI is measured as stocks or sales), they find that after controlling for country fixed effects there is either a small negative or insignificant

effect of treaty formation on FDI. The authors suggest that one possible reason for the non-promotion effect of treaties on FDI activity is that treaties reduce firms' abilities to evade taxes through transfer pricing or treaty shopping. An additional possibility for nonpromotion of FDI activity by new treaties is that treaties may increase investment uncertainty, at least in the short run.

Egger et al. (2006), who control for the endogenous selection of which treaties are actually formed, find that treaties significantly reduce FDI stocks. Davies et al. (2007) expand the research on this by utilizing affiliate-level data from Swedish-owned multinationals from 1965 to 1998. In line with earlier studies, they find no significant effect from treaty formation on the level of affiliate sales.

An important study from Neumayer (2006) finds, against all the results so far mentioned, robust empirical evidence that DTCs increase FDI to developing countries. However when the author splits developing countries into low-income and middle-income countries, he found that DTCs are effective in the group of middle income countries.

Just like trade diversion (Viner 1950), DTCs can create FDI diversion. Think of a simple case of a negatively sloped domestic demand schedule for capital, $K = f(r)$. Assume further that the domestic supply of capital is fixed at K^* . This implicitly determines the domestic autarky interest rate, $r^* = f^{-1}(K^*)$. Now suppose there are two foreign countries that can supply infinite amounts of capital, with $r_A + t > r^* > r_B + t > r_A$. Clearly, in the absence of any DTC that would eliminate the double taxation t , there would be capital imports ΔK from country B until $r^* = r_B + t$, with $\Delta K = K - K^* = f(r_B + t) - K^*$. The conclusion of a DTC with country A would change matters dramatically. Capital would no longer be imported from country B , but now from country A until $r^* = r_A$. There would be additional capital flowing into the economy (FDI creation) as $f(r_A) < f(r_B + t)$, but all the capital that previously arrived from country B will now be provided from country A (FDI diversion).

Selected Issues Concerning Double Tax Conventions

The application of double tax conventions raises numerous technical issues concerning the tax treatment applicable to cross-border situations. Such issues include the application of double tax conventions to dual resident companies and transparent entities, the concrete functioning of the arm's length method in transactions between associated enterprises, the inadequacy of the permanent establishment concept to the context of the digital economy and the protection of taxing rights of developing countries.

Our focus in this section is nevertheless on issues connected with base erosion and profit shifting, which have raised a serious concern on the effectiveness of the application of double tax conventions in connection with the exercise of national taxing sovereignty. From a structural perspective, insofar as double tax conventions are bilateral and negotiated in each case between two states, different conditions resulting from the negotiation unavoidably turn into an uneven set of rules. This creates the potential for cross-border tax disparities that in turn may give rise to unintended tax advantages, especially when taxpayers plan their affairs across the borders having that objective in mind.

A clear example of unintended tax advantages arises when the taxpayer pursues the application of a double tax convention in circumstances to which it was not meant to apply, thus abusing the tax convention, such as in the case of treaty shopping. Treaty shopping is a tax avoidance scheme targeting the reduction of source state taxation. For such purpose, cross-border investment is channeled through an intermediate company established in a treaty partner of the target state. Such a double tax convention limits the exercise of the taxing powers in the state of source more than what would otherwise apply under the domestic legislation of such country, or its double tax convention with the country of residence of the investor. This practice has significantly increased over the years and is countered through anti-avoidance rules contained in domestic legislation of the source state (general anti-avoidance

clauses usually drafted in the form of the principal purpose test, as well as various types of targeted and specific anti-avoidance clauses) and in double tax conventions (limitation-on-benefits clauses), including through the new Article 29 to be inserted in the 2017 Update to the OECD Model Convention. Such clauses essentially look at the function of the intermediate company and may limit the entitlement to the benefits of the double tax convention when such company lacks substance.

In principle, taxpayers have the right to arrange their affairs in a way that minimizes the tax burden, thus without any obligation to choose the most burdensome option from a tax perspective. However, international tax planning over the past decades has stretched this right to its extreme boundaries. Legal uncertainty concerning the tax advantages arising from the exploitation of cross-border tax disparities has contributed to prevent an effective solution to such problem.

Because of the size of this problem and its implications on the tax treatment of cross-border situations, the G20 has embarked on a global campaign against base erosion and profit shifting by multinational enterprises in the framework of the BEPS project. The implementation of this project is now steering international taxation and double tax conventions out of the traditional bilateral dynamics into a form of coordinated exercise of tax jurisdictions that secures consistency in tax treatment across borders.

The effects of the BEPS project on international taxation are manifold, including the obligation to counter international tax avoidance and aggressive tax planning through general, targeted and specific clauses also to be included in double tax conventions (Dourado et al. 2017; Krever 2016). This is steering double tax conventions towards a dimension in which they not only counter double taxation, but also its opposite phenomenon, i.e., double nontaxation. However, this conclusion should only apply to cases in which the Contracting States have not intended to produce this phenomenon. Therefore, even if the rules originating in the BEPS project support a fight against harmful tax competition, they should

not apply to cases when the Contracting States have intended to accept the existence of double nontaxation as one of the possible consequences of the allocation of taxing powers under the treaty. This is clearly the case of tax sparing, which leaves it up to the country of source to decide whether, when and at what conditions to exercise the taxing powers that the treaty has reserved to it. We consider this as particularly important in order to preserve consistency with the goals of the BEPS project. In particular, if the goal of the BEPS project is to allow the country of value creation to preserve the effectiveness of its taxing jurisdiction from erosion and profit shifting, this project should not prevent the source country from deciding not to exercise its taxing jurisdiction. This situation may often occur in developing countries in order to attract foreign direct investment and the measures of the BEPS project should not be used to allow the capital exporting country to tax income voluntarily forgone by the country of value creation. If that were the case, the BEPS project would in fact lead to opposite goals from the one that it officially pursues, harming the overall balance in the allocation of taxing powers under the double tax convention.

Another important point concerning the impact of the BEPS Project on double tax conventions with developing countries arises as to the settlement of cross-border disputes. The mutual agreement procedure has now turned into a minimum standard for double tax conventions, whose implementation is being secured through the multilateral instrument. Mutual agreement procedures are in essence a common forum for competent authorities of the Contracting States to reach a common view on technical issues concerning the interpretation and application of the double tax convention (and additional issues). However, developing countries lack capacity for running such procedures, especially when technical issues arise in relations with OECD countries, whose knowledge of technical issues is far more advanced. This type of problems in relations with developing countries would be even more difficult to address in the presence of arbitration clauses, which the BEPS multilateral

instrument only includes as a part of the optional content.

Why Do Countries Terminate a DTC?

The reasons for terminating a double tax convention may differ according to the country and context. Since OECD countries mainly conclude double tax conventions for enhancing the consistency in the exercise of taxing powers on cross-border situations, they also terminate such treaties for replacing them with new rules, which improve this situation. Whilst the conclusion of protocols fine-tunes the treaty to specific needs or problems, the termination of a treaty between OECD countries is an *extrema ratio*. Accordingly, it may occur when the two countries need to completely rediscuss overall conditions agreed (which for instance happened in the case of some economies in transition over the past decade), or when either country fails to execute the treaty in good faith.

Furthermore, in the relations with non-OECD countries the termination of treaties also occurs when either Contracting State feels that the conditions agreed are no longer suitable to achieve a balanced allocation of taxing powers. This occurred for instance when Germany felt that tax sparing clauses were no longer justified in the relations with Brazil, due to the considerable economic development of the latter country as compared to the moment in which those clauses had been negotiated in the framework of a package to promote economic development (Schoueri 2015). We may add here that a developing country should terminate a double tax convention when such country feels that the convention contributes to deprive it of the exercise of its tax sovereignty.

International Tax Coordination

Under the political mandate of the G20, the OECD has produced a dramatic change in the exercise of tax jurisdictions in order to counter base erosion and profit shifting. This project, better known as the BEPS project, was completed with the signature of the BEPS Multilateral Instrument

on 7 June 2017 and plays an important role for international tax coordination (Lang et al. 2017).

This development is important to achieve consistency in cross-border tax treatment, thus preventing the unintended tax advantages that result from the exploitation of tax disparities across the borders and countering tax avoidance more effectively.

The BEPS multilateral instrument should steer double tax conventions towards a much closer coordination of their content. In such context, bilateralism is not meant to disappear but will be exercised in a way that secures the effective countering of undesirable phenomena, such as tax avoidance and aggressive tax planning, along common schemes that constitute global minimum standards, from which states may not deviate. Furthermore, clauses constituting the BEPS minimum standards will no longer require negotiation by the Contracting States but simply apply as a direct consequence of the multilateral instrument. This development may bring double tax conventions back to their original function, which is to counter international double taxation by coordinating the exercise of taxing powers on cross-border situations, leaving it up to multilateral conventions to counter tax avoidance and aggressive tax planning with a single global instrument. There are already signs of a possible development in this direction.

The first sign is connected with tax conventions that regulate mutual assistance between tax authorities. This aspect has been long the object of one ancillary clause (Article 26) within double tax conventions for its instrumental function to securing the correct interpretation of tax treaties and domestic. However, after the establishment of a global standard on tax transparency, a rather large number of states have been showing an inclination to join the multilateral convention on mutual assistance in tax matters. This convention was drafted by the Council of Europe and the OECD, and currently allows for all methods of exchange of information (i.e., upon request, automatic, and spontaneous) and for additional procedures, including assistance in the recovery of taxes.

The second sign arises in the European Union, which is already moving in the direction of multilateralism on specific matters related to the implementation of the BEPS project with the EU Anti-Tax Avoidance Directive, issued on 12 July 2016 (1164/2016). The object and purpose of this Directive is to implement some aspects of the BEPS minimum standards in a potentially homogeneous way within the EU Internal Market. A possible future expansion of the directive can reduce the scope for tax treaties to regulate this aspect within the European Union, thus completing the process outlined above. A global multilateral convention against tax avoidance and aggressive tax planning can achieve a similar effect elsewhere, based on the understanding that one of the typical features of bilateralism is to have states negotiating the content of tax conventions. Therefore, insofar as they may no longer negotiate some aspects, there is also no need for a bilateral tax convention.

However, there are things that international tax coordination cannot and should not change. We refer hereby to the circumstance that the elimination of international double taxation is a structural goal of double tax conventions and this aspect should be tailored to the needs of bilateral relations.

Our view is that this conclusion should also apply and be adapted to the specific needs arising in relations with developing countries. In such context, double tax conventions have traditionally combined the elimination of double taxation with additional goals, in order to strike a fair balance for developing and developed countries when concluding a double tax convention.

For the reasons that we have indicated earlier, capital-exporting countries have a clear convenience in concluding double tax conventions. For capital-importing countries, concluding a double tax convention generally implies a loss of taxing powers and additional expenses connected with the obligation to supply more information to the one that they are interested in receiving. Until now, the application of mechanisms, such as tax sparing, has allowed turning double tax conventions into an instrument for those countries to remain the masters of their own international tax

policy decisions. Since the BEPS project was designed in order to protect the right of the country of value creation from base erosion and profit shifting, it should also be interpreted and adapted to the needs of countries that have the right to pursue their economic development without external interferences in their policy disguised under the need to counter international double taxation. Accordingly, the multilateral framework for combating tax avoidance and aggressive tax planning should make sure that any phenomenon of harmful tax competition is effectively countered. However, double tax conventions with developing countries should regulate all other aspects in line with what can be desirable for such countries and the developed country that is from time to time involved and they should do so without shifting taxing powers from the country of value creation to that from which capital originates.

An Economic Perspective for a Recurrent Issue: The Legitimacy of the Resale Right “I’ve been working my ass off for you to make all this profit. The least you could do is send every artist in this auction free taxis for a week.”

-Robert Rauschenberg to Robert Schull

NB: Schull originally bought the artwork \$900 in 1958 and resold it for \$85,000 in 1973 (quoted by Wu 1999, p. 531)

Abstract

Resale right consists of a small percentage of the resale price that art market professionals pay to artists at each resale of their works with the involvement of an auction house, gallery, or dealer. Until the new millennium, the resale right was implemented in a small number of countries. In 2014, more than 70 countries have resale rights. The United States, which has been very reluctant toward the adoption of the resale rights, seems to have changed its mind very recently. The debate about the opportunity to implement a resale right is commonly structured around two main axes. The first discusses whether or not visual artists profit from the resale right. The second deals with distortions of trade and competition within different countries that this right could create. While numerous governmental reports and academic research studies concern these two axes, focusing on the effects and consequences of the implementation of a resale right, fewer works deal with its economic rationale.

Synonyms

Droit de suite; Follow-up right; Resale right

Definition

Resale right consists of a small percentage of the resale price that art market professionals pay to

artists at each resale of their works with the involvement of an auction house, gallery, or dealer.

According to the legend, the story began in France with an engraving by Forain titled, “Un tableau de Papa,” depicting two ragged children observing a painting through a window. This scene, which is said to have inspired the resale right, referred to the sale of the *Angelus* by Millet at a record price. Millet originally sold this painting in 1860 for 1,000 francs to the Belgian painter Victor de Papeleu; in 1889, the copper merchant Secretan sold it for 553,000 francs (Fratello 2003), whereas his granddaughter lived in the greatest poverty, selling flowers in the street (<http://bibliotheque-numerique.inha.fr/collecton/12406-un-tableau-de-papa-lere-planche/>) (Fig. 1).

The resale right was at first established in France by the law of the May 20, 1920, and then reaffirmed in 1957 with the law on the literary and artistic property (article L122-8). This right was settled to recognize the particular situation of visual artists who sell their original works and therefore cannot make profit from copies as

Droit de Suite, Fig. 1 Jean Louis Forain (1852–1931) ‘Un tableau de Papa.’ Lithography

other artists usually do. According to the law, visual artists and their beneficiaries receive a small percentage of the resale price of their creation, for a limited period of time; each time their art work is resold through an art market professional. In the beginning, just auction houses were concerned; today gallerists, art dealers, or auctioneers are concerned. Moreover, this right is non-transferable and inalienable.

Belgium (1921) and Czechoslovakia (1926) soon implemented the French legislation adopting similar rules. Internationally, the Berne Convention for the Protection of Literary and Artistic Works included this right in 1948 (Article 14 bis and today article 14 ter because of different minor modifications) after the French proposed to add it to the convention in 1928 (Revision conference in Rome about the Berne convention). Nevertheless, its implementation remains optional, and reciprocity between countries is required for the right to be claimed: “[the right] may be claimed in a country of the Union only if legislation in the country to which the author belongs so permits, and to the extent permitted by the country where this protection is claimed.” Moreover, the convention pointed out “the procedure for collection and the amounts shall be matters for determination by national legislation.”

Practically, until the new millennium, the resale right was implemented in a small number of countries. In Europe, the resale right was enforced in nine countries of the 15 European Union (EU) Member States: Belgium, Denmark, Finland, France, Germany, Greece, Portugal, Spain, and Sweden enforced the right. In Italy and Luxembourg it was not applied because of the lack of precisions for an implementation. Four countries did not apply the resale right: Austria, Ireland, Netherlands, and the United Kingdom. Moreover, practices differed greatly regarding the minimum threshold, the rate in force, the sales concerned (only public auctions in Belgium and France), and even the management of the rights (mandatory, collective, or individual) (Raymond and Kancel 2004). Outside of Europe, some countries had introduced the right in their law, but without an effective implementation. This

was the case of Brazil, Paraguay, Uruguay, Asia, Mongolia, and the Philippines. This right was not recognized in leading places for the art market, notably in the United States, except in California. Mexico and Venezuela were the rare countries outside of Europe that implemented resale rights.

At the turn of the millennium, different events reactivated the debate. In 1996, the European commission proposed a new directive to harmonize the practices in Europe and the Council adopted it in July 2001 (article 48 of the DAVSI Law implementing the directive 2001/84/EC). It plans the payment of royalties on the basis of a scale beginning at 4% for works of art over 3,000 euros to 0.25% for works worth over 500,000 euros and up. All professional resales are affected auction and gallery sales. Moreover, the right is transferred to the heirs for a period up to 70 years after the artist's death. The total amount of the right payable to the artist or his family cannot exceed 12,500 euros. Some adaptations had been allowed in some countries that did not recognize the right previously, notably in the United Kingdom where its adoption had been controversial; during initial implementation, the right only applied to living artists. It has been extended to heirs of deceased artists from the beginning of 2012.

In Europe, the new law brought about many discussions in countries that had previously supported the law, such as France, because of its extension to art galleries. Obviously, the debates had been even stronger in countries such as the United Kingdom, a crucial area for the art market, where the right was not recognized prior to that time (Dallas-Conte and Mc Andrew 2002; Ginsburgh 2005, 2008; Kirstein and Schmidtchen 2001; Pfeffer 2004).

Despite these disputes, a growing number of countries have followed Europe. Today, more than 70 countries have resale rights. The right has been in effect in Australia since June 9, 2010 (George et al. 2009). In China, a specific clause is included in the draft of a new copyright law soon to be submitted to China's State Council, the country's cabinet. China's first copyright law took effect in 1991; the latest draft brings the country closer into line with prevailing European

and American standards. And the United States, a major player in the contemporary art market, which has been very reluctant toward the adoption of the resale rights (Landes 2001), has changed its mind very recently. Indeed, a report published in December 2013 by the US Copyright Office recommends Congress to consider enacting a resale royalty for visual artists. The same organization had declared in 1992 (Claggett et al. 2013), when it had last considered the subject that it was “not persuaded that sufficient economic and copyright policy justification exists to establish resale right in the United States” (Register of Copyright 1992, p. 149). Up to now in the United States, California has been the only state to apply this right, in a soft version, i.e., when the release price records an increase exceeding \$1,000. Currently, the situation could evolve favorably.

The debate about the opportunity to implement a resale right is commonly structured around two main axes presented below. The first discusses whether or not visual artists profit from the resale right. The second deals with distortions of trade and competition within different countries that this right could create. While numerous governmental reports and academic research studies concern these two axes, focusing on the effects and consequences of the implementation of a resale right, fewer works deal with its economic rationale as it is shown in the last section.

Resale Rights: Significant or Lackluster Profits for Visual Artists?

Discounting Effect

Resale rights are introduced in order to increase the artist earnings. Nevertheless, such an introduction tends to lower the market price of first sale. Under a hypothesis of rational expectation, research shows that the buyer takes into account the resale royalty he will pay in the future and then deducts its discounted value from the initial price he would have accepted to pay without such a right. Thus, the wealth an artist can expect from his initial sale is lowered (Filer 1984; Karp and Perloff 1993; Mantell 1995; Perloff 1998).

In the long term, profitability depends on the artist's tolerance of risk. If he is risk adverse, then the introduction of a resale right can induce two negative consequences. Firstly, the artist has no choice but to accept a risky lottery instead of a sure income. And usually, it is easier for collectors compared to artists to bear the risk, because they are often wealthier and more able to diversify their portfolio (Filer 1984; Karp and Perloff 1993; Mac Cain 1994). Secondly, there is what Kirstein and Schmidtchen call a paradox of “risk aversion.” That is to say the artist's lifetime utility may be lowered even if the resale royalty and the incentive effect had a positive net effect on his monetary lifetime income. This result appears when the income of the artist increases over time. Due to risk aversion, the utility function is concave; an additional euro when the income is low can bring more utility compared to when the income is already high (Kirstein and Schmidtchen 2001).

Nevertheless, the hypothesis of risk adversity is controversial. Many studies show that a growing number of artists enter the occupation even if the income distribution is strongly biased toward the lower end of the range. An explanation could be that artists are true risk lovers or that there is a probabilistic bias (Menger 2006), meaning that artists overestimate their chance like lottery players. The other explanations are as follows: artists are “committed to a lobar or love” or “rational fools” (Menger 2006, p. 776). More recently, Wang (2010) showed that the introduction of resale rights increases the artist profit, but lowers the consumer surplus, the whole effect on the social welfare being negative.

Collection Costs

The costs of the implementation of the system are usually deducted before the distribution of royalties. Then, the benefit for the artists might be lowered by important collection costs. According to some authors, these costs are quite high (Ginsburgh 2008; Graddy et al. 2008), whereas others underline the equivalence with perception costs for other intellectual rights, between 12% and 17% in France and 15% in the United Kingdom (DACS 2008; Farchy 2011). The European

Commission came to a similarly ambiguous conclusion in its last report (2011). Whereas some inefficiency in the administration of the system in some countries is recorded, the conclusion remains optimistic, underlying the necessity for an exchange of best practices.

Few Winners

Moreover, as discussed above, cultural markets are structured as stardom markets. Small differences in talent lead to huge differences in earnings, “Sellers of higher talent charge only slightly higher prices than those of lower talent, but sell much larger quantities; their greater earnings come overwhelmingly from selling larger quantities than from charging higher prices” (Rosen 1981). An immediate consequence for the art market is that a large percentage of artists will never benefit from the resale market. Available data about the resale rights distribution among artists support this phenomenon in Australia (Stanford 2003). More recently, a study about the United Kingdom art market in 2006/2007 showed an average payment per work of £693; nevertheless, for 85% of the items, the average payment per work was only £249 versus £3,430 per item for the remaining 15% (Graddy et al. 2008). Other data confirm this disparity. In the United Kingdom, 60% of the artists who received a right earned less than 24£ per artworks, whereas 2% of the artists earned more than 50,000£ (DACS 2008). In France, on the average 68% of the artists earned 1,114 euros, while only 1% earned 15,908 euros. Moreover, the percentage breakdown of sales (in value) submitted to the resale right is 74% for deceased artists and 26% for living artists (Farchy 2011).

Unwaivability, Two-Sided Effects

Another ambiguity lies in the unwaivability of the resale right (Hansmann and Santilli 2001). Some people argue that this unwaivability is necessary for protecting the artist against an unbalanced negotiation with gallerists. A limited number of gallerists face the vast population of artists. Due to the asymmetry of bargaining power, gallerists pay the minimum to the artists, who have no choice

but to accept. According to this reasoning, the discounting effect described in the previous section cannot happen; gallerists cannot lower the price on the first market with a resale right because the price is already fixed at its minimum. Consequently, the resale right is finally helpful for artists. The difficulties of the Projansky agreement could illustrate this unbalanced negotiation and the need for unwaivability. According to this agreement, the artist benefited from some moral rights and would receive 15% of the appreciated value each time a work was transferred; nevertheless, despite a large publicity, this agreement did not encounter a large success. There is also a downside of unwaivability. Notably, it deters artists to indicate the quality of their artwork. According to the theory, the more an artist trusts in his production, the higher the resale right he requires (Hansmann and Santilli 2001). Nevertheless, as the authorities fix the later, this indication is no longer relevant.

Visual Artists' Earnings in Relation to Other Cultural Workers

A central claim for the resale rights rationale is that visual artist cannot benefit from usual protection provided by copyright (reproduction, representation, etc.) as other artists do. A comparison is not easy to conduct because the business models of the other cultural areas differ due to the nature of the product. Recent data offer records of the median wages and salaries of fine artists (including painters, sculptors, illustrators, and multimedia artists, but excluding photographers and graphic designers), writers and authors (including advertising writers, magazine writers, novelists, playwrights, film writers, lyricists, and crossword puzzle creators, among others), and musicians. While visual artists appear poor (\$33,982) by comparison to writers and authors (\$44,792), they are better off than musicians \$27,558 (Nichols 2011). Data from the US BLS confirm that visual artists' earnings are not lower than other creative industry professionals; the median annual wage is \$44,850 (\$54,000 for the mean) for visual artists, \$55,940 (\$68,420 for the mean) for writers and authors, and \$47,350 (\$53,420 for the mean) for composers.

Resale Right: Gravel or Sand in Market Mechanisms?

Distortions of Competition on the International Art Market

The implementation of a resale right increases transaction costs and theoretically possibly reduces the competitiveness of a given country if its competitors do not apply such a right. Indeed, for valued artworks, the expected resale right may overstep sometimes transportation fees so that delocalization of sales appears as profitable.

This argument was at the heart of the European community concerns in 2006 when it decided to harmonize the resale right in Europe. Indeed, the resale right was considered as a crucial factor “which contributes to the creation of distortions of competition as well as displacement of sales within the Community” (European Commission 2011, p. 3). The United Kingdom fought this extension. They did not apply the resale right previously due to the risk of losing competitiveness among other European countries, as well as the United States, all of which are leaders in the art market.

In practice, findings suggest that these concerns were ill-founded. No evidence has been found on a weakened position of the United Kingdom in the international art scene. Surprisingly, according to a study conducted by the IPO, just after the introduction of the resale right, the proportion of eligible works to the resale right in the United Kingdom increased, so did their prices (comparison of the period 2006/2007 with 2003/2004). In the short term, it appears that the implementation of the resale right in the United Kingdom did not have a negative impact on the relative position of its market compared to other countries (Banternghansa and Graddy 2011; Graddy et al. 2008). Conclusions of an EU report in 2011 are less optimistic because of the decrease of the UK’s market share on the international scene between 2008 and 2010 from 34% to 20%. Between 2005 and 2010, UK’s market share decreased from 27% to 20%. Nevertheless, in the same period, the US market share also declined from 54% down to 37%, whereas China

increased its share from 8% up to 24% (European Commission 2011).

Distortions of Competition Between Auctions and Galleries?

Resale right also has indirect effects. The international competition among auction houses depends on their ability to attract sellers and valuable items. Then, in 2007 Christie’s France shifted the economic burden of the royalty from seller to buyer. Nevertheless, such a shift was considered as anticompetitive behavior because an auction sale seemed more attractive to sellers than a sale through a French dealer. Indeed, at auction a seller would receive the hammer price without the deduction of the resale royalty, the latter being paid by the buyer. Whereas with a French dealer, he would receive the price less the resale royalty because dealers charged the resale royalty to the seller according with French law. According to this reasoning, the French Association of Antique Dealers took action against the auction house; the French court of Appeal took the view that parties are not allowed to shift the economic burden of the resale right from the seller to the buyer.

From an economic point of view, and according to auction theory, the buyer bids up to his reservation price. Then, if a resale right is introduced, the buyer will reduce his reservation price by an equivalent amount. The situation is equivalent for the seller regardless of the method of sale used.

Distortion of Competition Between the Art Market and Financial Market?

The relative attractiveness of the art market compared to the financial one is reduced because of an increase in transaction costs. Collectors act on a medium- or a long-term basis and do not necessarily plan to resell their artwork, whereas speculators have short-term views and are motivated by the increased value they will obtain when they resell the item (Kakoyiannis 2006). Thus, an indirect effect of the introduction of the resale right could be to “clean prices,” bringing market prices of artworks closer to their fundamental artistic value.

Resale Right: Is There Any Need to Correct a Market Failure?

Consequences of the Physical Embodiment of the Creation for Visual Art

The main economic rationale that sustains the general copyright lies in the necessity to correct a market failure and the public good property of a creation (nonrivalry and nonexclusivity). This is due to the split existing between a work and its material embodiment. Once a creation is disseminated, anyone can appropriate it and reproduce it at a low marginal cost. Without protection, the risk is high for the creator to not recover his initial investment. Curiously, for visual artists and in the case of the resale right, the idea originally put forward is that because of the uniqueness of the creation they produce, visual artists do not benefit from reproduction rights in the same way as other artists do; above all, the aim of the resale right is to “ensure that authors of graphic and plastic works of art share in the economic success of their original works of art” (European Directive). Nevertheless, for visual artists, the market failure does not exist because the public good property of the creation disappears; no one can copy the creation without sustaining a significant marginal cost. As a consequence, it is not necessarily to artificially create a monopoly for the visual artist on his creation because, by nature, the creation and its physical embodiment are intertwined and uniqueness is one of the major characteristics of the art market. Moreover, prices of different artworks produced by an artist are linked and depend on the artist’s reputation. Then, it does not seem necessary to protect an artist; if the value of one of his artworks goes up, he just has to sell another one on the market to increase his profit. It is a well-known law that on the art market, in the very beginning of an artist’s career, supply exceeds demand, whereas rationing can appear on the market with queuing phenomenon as the artist obtains fame. In other words, if the market power of the artist increases along with his reputation, then it will be easy for him to earn money selling another piece.

Externalities of Future Artworks on Current Ones

If there is a need to correct a market failure with the resale right, it could be the externalities of future artworks on the current ones. Indeed, the artistic recognition of an artist depends on his whole production. Depending on the quality of future artworks, the prices of the current ones can evolve in the future, positively or negatively. These externalities are not taken into account. Because of such failure, there can be underproduction in case of positive externalities. The introduction of a resale right could be a means to internalize these externalities. Nevertheless, the law only considers positive externalities and increases in prices, but not negative ones. If in the future the artist produces artworks of lesser quality, these will lower his global reputation and produce a negative externality for the future market of current artwork. The resale right does not take into account such a negative externality; thus, a risk of overproduction appears.

Visual Art: A Durable Good Monopoly Issue?

Some economists studied the issue from a symmetrical point of view, analyzing if resale royalties have incentive effects on the artists’ output of subsequent decisions. The artist produces a durable good, and when managing his market power, he encounters a dynamic consistency problem of “competing with one’s future self” (Solow 1998). Resale right effects depend on the nature of future artworks; if they are substitutes of current artwork, then the resale right will have a negative impact with a decrease in the artist’s production and an increase in prices. Conversely, if future artworks are complementary, there is an incentive for the artist to increase its production (Solow 1998). In Solow’s analysis, the artist is supposed to be “price setter,” i.e., only well-known artists are able to set their price in the first period. Wang extends the analysis considering not only well-known artists but also new artists (price takers). In both cases, the consequence of the introduction of a resale royalty is to lower the global production and to increase the artist’s lifetime profit. Nevertheless, the rise of the artist’s profit remains

questionable as social welfare globally decreases (Wang 2010).

Resale Right, “Much Ado About Nothing?”

Not only do market failures really apply in the visual arts market, but also resale rights create disincentives for a crucial intermediary for artist recognition, the gallerist (Moulin 1994). Since the beginning of the twentieth century, the art dealer has become a crucial intermediary for the artist’s legitimacy in the market. This changes the analysis significantly. Indeed, under the assumption that the promotion of the value of an artist’s work depends both on the efforts of the artist and of the dealer, it is shown that a specific royalty, i.e., a “share cropping” contract, could be positive. However, assuming that the promotion of the artwork’s value depends solely on the dealer, the resale right is totally counterproductive (Kirstein and Schmidtchen 2001).

It is difficult to draw a clear conclusion. Both the benefits and costs are lower than expected, and then a balance between the two parts becomes plausible. But at the same time, why discuss a government intervention on the market when real market failure does not affect the art market? Probably, the record of lower costs than initially expected and the symbolic reward given to the artist through the resale right help explain the general movement for its implementation on an international level. Nevertheless, it is important to take into account the role of imitation; we know that imitating the actions of others can be a rational behavior to improve one’s own information in case of uncertainty. The last US Copyright Office report seems to adopt such a rule when writing “at the same time recent developments – including in particular the adoption of resale right laws by more than thirty additional countries since the Office’s prior report – would seem to warrant renewed consideration of the issue.” Nevertheless, one must be careful and keep in mind that imitation can also lead to a misinformed cascade of followers, causing the vast majority of the population to make bad decisions (Bikhchandani et al. 1992).

Abstract

Drug prices are regulated in a legal framework that organizes the negotiation between pharmaceutical firms and a third-party payer

responsible for healthcare reimbursement. This regulation aims at compensating for market failures associated with drug specificities. Explicit economic reasoning through the so-called health technology assessment framework is increasingly embedded in the institutional and administrative process of the evaluation procedure leading to market access, pricing and reimbursement for new drugs.

Definition

Drug prices are regulated in a legal framework that organizes the negotiation between pharmaceutical firms and a third-party payer responsible for healthcare reimbursement. This regulation intends to optimize the use of limited public resources in the provision of healthcare. Private market pricing would fail to adequately take account of the specificities of medicines as vectors of health improvement.

Regulatory tools are thus necessary to ensure that the allocation of resources to medical interventions is welfare enhancing. An increasing number of countries have adopted regulation laws for the reimbursement of drugs that rest not only on medical prerequisites but also increasingly on cost-effectiveness requirements and budget impact analyses. Explicit economic reasoning through the so-called health technology assessment framework is increasingly embedded in the institutional and administrative process of the evaluation procedure leading to market access, pricing, and reimbursement for new drugs.

Why Should Drug Prices Be Regulated?

This question is rooted in the broader setting of healthcare provision. Healthcare comprehends “those goods and services whose primary purpose is to improve -or prevent deterioration in- health” (Hurley 2000, p. 67). As a medical intervention, healthcare consists of procedures (e.g., surgery), care (e.g., nursing and care follow-up), programs (e.g., screening or vaccination), drugs and medical devices, etc. It is also an economic good as it is

provided in a context of scarce resources compared to their potential uses. There is thus always an opportunity cost to allocating resources to a specific use and giving up the advantages of waived alternatives. Healthcare is a combination of rival and exclusive private goods: for instance, individual treatment is rival, and drug pricing may prevent access to it. In this context where drugs are taken as economic and private goods, and at first glance, private market pricing could appear as a natural candidate for an efficient allocation of resources.

However, characteristics pertaining to the specific nature of healthcare and pharmaceuticals – these are not standard market goods – preclude private market pricing. Market mechanisms for resource allocation rest, among other things, on individual preferences, as the consumption of private goods directly impacts individuals' utility. Healthcare and more specifically medicines do not as such provide utility, as in the case of painful treatments, because the desired commodity is not medical consumption but health improvement. Painkillers or adverse side effects constitute an exception as they directly affect utility while they also contribute, if the treatment is eventually more effective than harmful, to health improvement. The demand for healthcare and drugs is fundamentally a derived demand for health (Grossman 1972). Since health is neither tradable nor transferable, the demand-supply framework for valuing goods, in this instance, pharmaceuticals, through market prices is not suited. Health is thus a primary commodity that requires the consumption of goods and services, among which are drugs, along with other determinants with individual and collective dimensions such as lifestyle, genetic endowment, education, and safe environment, among the most important.

An optimal market equilibrium is such that “if a competitive equilibrium exists at all, and if all commodities relevant to cost and utilities are in fact priced by the market, then the equilibrium is necessarily [Pareto] optimal in the following precise sense that there is no other allocation of resources to services which will make all participants in the market better off” (Arrow 1963, p. 942). Drug and healthcare specificities prevent

competitive market pricing from optimally allocating healthcare resources. However, non-competitive mechanisms for resource allocation, such as drug price regulation, can be welfare improving, which thus call for nonmarket interventions.

Not only healthcare needs cannot be anticipated, but the consequences of healthcare consumptions in terms of life expectancy, future consumption and utility, labor supply and productivity, healthcare provision level, and scope are uncertain (Meltzer 1997). The immense variety of health risks and informational asymmetries (adverse selection into insurance schemes, uncertainty about the individuals' risk profiles, moral hazard in health-related behavior) impede the establishment of a comprehensive competitive insurance market system. In addition to these aspects, the system may face unsustainable risk-bearing markets as in the case of orphan diseases or pandemic noncommunicable diseases like type 2 diabetes. As a consequence, the need for regulation of insurance access is often typically addressed through risk pooling by a third-party payer (Morris et al. 2007): individual insurance premiums feed a common fund managed by that third-party responsible for reimbursing healthcare providers once they have provided treatment to patients.

The healthcare sector is also characterized by substantial externalities, as, for instance, in immunization against communicable infectious diseases or through the productivity improvement associated with enhanced health status in the general population. In addition, current demand does not fully reflect potential demand: the availability of healthcare (e.g., through the permanent presence of hospitals) is valued as such and separately from its actual usage given the infrequent nature of medical interventions. The internalization of those external effects requires nonmarket institutions. Finally, asymmetric information between producers and patients-consumers mostly occurs during the physician-patient encounter. The need for drug licensing and control of prescription practices arises from the fact that patients' interest may be balanced with manufacturers' profit and physicians' own welfare, thus creating a risk of

supplier-induced demand and biased medical prescription.

As a consequence, drug provision calls for price regulation and public intervention. How are these aspects grounded in economic theory? More specifically, how is drug regulation related to health technology assessment standards, namely, cost-effectiveness and budget impact analyses? What are the institutional translations of such regulatory requirements?

How to Regulate Drug Prices?

One should distinguish between the control of the provision of prescription drugs to patients and the regulation of their price. The regulation of drug supply aims at several purposes. From a public health perspective, it is meant to guarantee a minimal level of quality and safety of the product in itself as well as in its usage by the various potential subgroups of patients. In this respect, the main tool of regulation is the marketing authorization based on clinical trials, but production is controlled and safety still monitored while the drug is marketed. The distribution of prescription drugs is usually authorized for a monopoly of chartered pharmacists, advertisement is controlled, and indications can be limited through guidelines. Mandatory and optional insurance schemes define the perimeter of reimbursed medicines. Early access to innovation is increasingly facilitated through compassionate use programs or dedicated patient access schemes, while in the meantime, following sanitary scandals in the past decades, the strain on product safety agencies has increased toward maximal safety guarantee. From a macro-economic perspective, the supervision of drug provision intends to ensure the sustainability of total health expenditures while encouraging innovation through the patents system, antitrust regulation, and public funding for fundamental clinical research. Transnational regulations in healthcare remain limited (examples are the European Marketing Authorization or the international protocols for clinical trials), and countries still differ in their institutional choices. The regulation of prescription drugs remains largely national as it reflects

differing social insurance choices and is, to some extent, embedded in cultural preferences.

Drug price regulation is meant to ensure that once a new drug has been assessed with a significant degree of medical efficacy and improvement compared to the existing drugs with similar therapeutic indications, the outcomes of its use are worth the cost incurred by the third-party payer. Health technology assessment provides methods for the economic evaluation of disease treatment and follow-up or of prevention by screening or vaccination (Drummond et al. 2015). The two main methods are cost-effectiveness analysis and budget impact analysis.

Cost-effectiveness analysis compares the relative costs and outcomes of two or more strategies (or treatment options) competing for the implementation of a health program. Contrary to cost-benefit analysis, it does not use an estimation of the equivalent money value of the outcomes. The standard measure of effectiveness is the number of life years gained by the patients, which can be adjusted by the quality of life in order to produce a cost-utility analysis. Cost-effectiveness analysis is both comparative (selecting a strategy implies that the net advantages of the waived ones are given up) and consequentialist (the focus is on maximizing the outcome from the available resources). This opportunity cost approach was initially conveyed through the incremental cost-effectiveness ratio. Its numerator expresses the cost difference when moving from one strategy to another, and the denominator is the difference in effectiveness. The ratio is then compared to the collective or decision-maker's marginal willingness to pay for an additional unit of effectiveness. One strategy will be preferred to another if its incremental cost-effectiveness ratio is lower than the collective willingness to pay or efficiency threshold. If no such value is available or if the decision-maker wishes to consider a range of thresholds then a second and more general indicator, the incremental net benefit provides a linear rearrangement of the incremental cost-effectiveness ratio. It is the subtraction of, on the one hand, the difference in effectiveness valued by a predefined collective willingness to pay from, on the other hand, the difference in costs.

If the incremental net benefit is positive, then the switch to the new strategy is accepted. When comparing several strategies for a given threshold, the one with the highest benefit should be selected.

The simultaneous comparison of all the competing strategies can be summarized in an efficiency frontier that plots differential effectiveness against differential cost with the least effective treatment option as the reference and origin of the graph. The method allows discriminating between efficient (cost-effective) strategies located on the frontier and those out of the frontier. The latter are said to be “strictly dominated” if they yield higher cost and lower effectiveness than another strategy. They are subject to “extended dominance” if their incremental cost-effectiveness ratio is greater than that of the next more effective strategy. The efficiency frontier allows sorting treatment options independently of any specific value of collective marginal willingness to pay.

The second method in health technology assessment is budget impact analysis (Mauskopf 1998; Mauskopf 2014; ISPOR 2014). It examines the extent to which the introduction of a new treatment option in addition to the existing ones affects the third-party payer’s budget. The new strategy may contribute to reshuffle the supply shares in the set of treatment options, change outcome achievements, as well as the expected mid-run budget burden. The budget impact is calculated as the difference between the expenses borne by the third-party payer before and after the introduction of the new drug and the associated treatment option.

How Is Health Technology Assessment Used in Drug Price Regulation?

Health economic evaluation for efficient resource allocation is steadily promoted by international joint actions like the European Network for Health Technology Assessment (EUnetHTA) including 33 countries among which are Russia and northeastern nations. Twenty-five of them have issued one or several methodological

guidelines (Heintz et al. 2016). They are directed to pharmaceuticals specifically or have a more general purpose including all types of healthcare technologies. For the vast majority of them, their purpose pertains to reimbursement or price negotiation with only a handful of guides with a scope limited to information. A majority of guidelines has a mandatory status as opposed to the less stringent “recommendation” status. In what follows, we review a number of country case studies as representative, but not exhaustive, of the contrasted pathways that can be followed by drug price regulation institutional processes.

England is the historically leading proponent of the inclusion of health technology assessment into the process of healthcare resource allocation. After attempts at efficiency analysis as far back as the early 1970s, the creation in 1999 of the National Institute for Clinical Excellence (NICE) constitutes a landmark and the institutional recognition that the admission of drugs to reimbursement should be grounded on both medical and economic appraisal. The Health and Social Care Act of 2012 has extended and reinforced NICE (incidentally, the same acronym now stands for National Institute for Health and Care Excellence), with an emphasis on recommendations on the uncertainty surrounding the efficiency of the evaluated drug or medical device. Assessments are conducted by the pharmaceutical companies and appraised by NICE in reference with guidelines periodically published. The evaluation rests on the calculation of an incremental cost-utility ratio expressed in cost per QALY. Health technology assessments admittedly have little leverage in the financial negotiations between the National Health Service (NHS) and the manufacturers in the framework of the 5-year Pharmaceutical Price Regulation Scheme. However, they are crucial as they determine the set of healthcare services included in the NHS reimbursement design (Chalkidou et al. 2009; Sorenson and Chalkidou 2012). In contrast with almost all other countries using cost-effectiveness evaluation, NICE explicitly refers to a decision threshold set between £20,000 and £30,000 (McCabe et al. 2008). Any submitted new drug or medical device is either integrated into that scheme, rejected, or

subjected to additional clinical or economic data collection.

In France, cost-effectiveness analysis plays an increasing role in the price negotiation process, compared with England, in a progressive attempt to reconcile healthcare quality and sustainability. The National Health Insurance Reform law of 2004 created the French National Authority for Health (*Haute Autorité de Santé*, HAS). The process was later finalized by the 2012 Social Security financing law and its application decree relative to the health-economic mandate of HAS. Since October 2013, the economic evaluation and public health committee of HAS provides the interministerial Healthcare Products Pricing Committee (*Comité Economique des Produits de Santé*, CEPS) with a cost-effectiveness opinion on those drugs and medical devices which are expected to have a significant medical benefit and impact on the health insurance budget. Reimbursement decisions by the national health insurance scheme are based on the actual clinical benefit and the added clinical benefit with regard to existing treatment options, as appraised by the HAS medical committees. Cost-effectiveness opinions are used by the CEPS, together with other criteria (added clinical benefit, price of comparators, expected sales volume, and European reference price) in the price negotiation process. A feature of economic appraisal that France shares with England and several other countries is the growing interest in the exploration and documentation of uncertainty surrounding the cost-effectiveness outcomes of the manufacturers' submissions. Indeed the greater that uncertainty, the weaker should the price claim be.

The German regulatory framework for pharmaceutical prices currently rests on a strict assessment of clinical benefit (through the so-called early benefit assessment procedure) and a posteriori cost-containment measures. It is characterized by a quasi-absence of health economics criterion, despite several attempts by the regulatory power to include cost-effectiveness assessment for medicines (Klingler et al. 2013). The Institute for the Quality and Efficiency of Healthcare Services (*Institut für Qualität und Wirtschaftlichkeit im Gesundheitswesen*,

IQWiG) was created in 2004 as an independent scientific body for health technology assessment. In the 2007 Statutory Health Insurance Act to Promote Competition (§35b), IQWiG was explicitly given the objective to set maximum reimbursement prices for pharmaceutical and non-pharmaceutical products. The landmark 2010 Pharmaceutical Market Reorganization Act (AMNOG) however substantially reduced the role of health economics evaluation and set forth the importance of drugs clinical assessment as a criterion for the price negotiation between the pharmaceutical firms and the Federal Joint Committee (G-BA). Health economics evaluations conducted by IQWiG now amount to interventions of the last resort, to which recourse may be sought by the Federal Association of Sickness Funds or by a drug manufacturer, following a failure in price negotiations and a decision by an arbitration committee.

Beyond the current sound financial situation of the sickness funds, several historical and ethical factors have been invoked in the literature (Klingler et al. 2013; Gerber-Grote et al. 2014) to explain the reluctance to give economic evaluation a more substantial role in the German drug regulation system. Incidentally, despite the absence of a formal role for efficiency evaluation, medicines, even patented medicines, that fail to demonstrate additional clinical benefit cannot obtain higher prices than their comparators, by virtue of the reference pricing procedure.

Health coverage is fragmented in the United States of America, with a historically high level of private activity and a shared power between federal and state governments regarding healthcare regulation. The use of cost-effectiveness analysis exemplifies the decentralized organization of healthcare provision and coverage. Drugs are mainly regulated at the federal level to guarantee effectiveness and safety (Rice et al. 2013). A fast track process designed by the federal Food and Drug Administration facilitates early access for patients to drugs addressing unmet needs. In contrast, the regulation of prices varies widely among health insurance systems. Health coverage is divided between private employment-based or direct-purchase insurance and welfare programs,

mainly Medicare (covering people over 64 years), Medicaid (covering people with low income), and the State Children's Health Insurance Program. Prescription drug prices are not directly regulated. The price and patient-co-pay for a given drug vary and depend on the insurance plan that covers the expense. Importation of drugs from a country in which drugs are sold at a lower price is prohibited in the United States.

Regarding Medicare, private plans compete on costs and coverage and separately negotiate drug prices with pharmaceutical companies (Walton et al. 2017). The noninterference clause stipulates that the federal administration for health may not interfere with the negotiations between drug manufacturers, pharmacies, and plan sponsors. The Federal Medicaid Drug Rebate Program, for which pharmaceutical firms must apply to have their drugs reimbursed, guarantees that Medicaid, as well as the Department of Veterans Affairs, will not be charged more than the lowest price available to private payers; most states negotiate further rebates for Medicaid drugs plans (Rice et al. 2013).

Health Technology Assessment is remarkably referred as "comparative effectiveness research" in the United States and rarely includes cost-effectiveness evaluation. It is mostly performed by insurers, pharmacy benefit managers, and non-profit organizations including the Patient-Centered Outcomes Research Institute (PCORI) created by the Patient Protection and Affordable Care Act (Chalkidou et al. 2009). The 2010 Patient Protection and Affordable Care Act states that cost-benefit analyses are not allowed for healthcare practice or reimbursement in the Medicare program. However, cost-effectiveness has been successfully established in other areas of health administration: Veterans Health Administration and the Military Health System conduct health technology assessments on pharmaceuticals, operated by the Pharmacy Benefits Management Strategic Healthcare Group and the Department of Defense Pharmacoeconomic Center. States as well can perform or commission cost-effectiveness evaluations to support Medicaid programs administration. The development of the private Institute for Clinical and Economic

Review reveals the demand for cost-effectiveness evaluation in a context of high-price therapeutic innovation (Walton et al. 2017). Eventually, cost-effectiveness evaluation is also performed by the pharmaceutical industry itself, partly to address foreign national regulatory requirements.

Budget impact analysis is currently mandatory in less than 20 countries including Germany, Malaysia, Mexico, Norway, Poland, Thailand, etc. It is still often viewed as a complement to cost-effectiveness analysis and, as such, substantially varies in the extent to which it follows international methodological recommendations (ISPOR 2014). Examples of such flaws in the case of the USA are provided by Mauskopf and Earnshaw (2016). However, when adequately performed, budget impact analysis does provide an outline of the financial burden that is likely to be faced if the evaluated product is to be added to the existing set of interventions. Admittedly, market shares after the introduction of the new drug are subject to structural uncertainty; it remains true that financial projections provide indispensable estimations of the impact on annual healthcare budgets and population health.

The total budget effect of introducing a new treatment option among existing ones naturally questions the affordability and sustainability of the corresponding financial effort. In this respect, budget impact analysis is descriptive rather than prescriptive: it provides information (undeniably surrounded by uncertainty) to the third-party payer, but does not infer any decision from it. The decision is left to the health insurance agency to accept or not the new product into the reimbursement scheme and at what price. In the case of highly expensive innovative drugs, even a relatively small number of patients can nevertheless bear a significant budget burden. For non-communicable and especially chronic diseases with high prevalence and growing incidence, comparatively small drug price variations can have a huge budgetary impact.

Questions about the affordability and sustainability of healthcare innovations are also present in the practical implementation of cost-effectiveness analysis. Incremental cost-effectiveness ratios consider the collective willingness to pay as a

parameter against which decision is made to switch to the new treatment strategy if the ratio is below the efficiency threshold. The incremental net-benefit approach considers the threshold as a variable, but a decision cannot be made without defining a precise value or range of values of collective willingness to pay. The efficiency threshold is thus, in theory, crucial for decision-making. In practice, however, a majority of countries does not provide a value for this threshold, or if it does, it is susceptible to many exceptions (innovative cancer treatments, orphan diseases, etc.). Methodological ambiguities are here reflected in institutional (non)-choices. More than the expression of citizens' willingness to pay, represented by the third-party payer protecting them as patients, the efficiency threshold is a matter of marginal productivity of healthcare provision and opportunity cost in a given macroeconomic context. In times of expansion, the threshold should increase; a lower value would accompany periods of budget contraction. There should also be a trend toward lower values as the productivity of the healthcare system increases: efficiency requirements for new treatments should be more stringent; otherwise the opportunity cost of their adoption would increase. In practice, there is a general trend in most countries to accept the reimbursement of innovative drugs with increasingly higher incremental cost-effectiveness ratios compared to existing treatments. This acceptance could reflect the choice of citizens or at least of decision-makers to give more weight to other legitimate criteria than the efficiency.

Conclusion

Since health is a primary commodity whose characteristics cannot be reduced to those of a private good, provision of healthcare cannot be left to private markets only. The ensuing regulation of healthcare prices and specifically of drug prices increasingly involves assessments by national evaluation agencies more or less dependent on the government. The methodological framework for national regulations usually abides by international recommendations, even though the national political and administrative context remains

significant in the shaping of the evaluation process. The legal framework for the assessment protocol explicitly includes economic reasoning, which is quite innovative in the broader field of public intervention where concerns about efficient resource allocation are often absent from the decision-making process. The rationale behind this explicit and legally binding inclusion of both medical and economic criteria has sometimes stemmed from budgetary pressures due to the contraction of available resources as well as from political pressure to rationalize the use of scarce collective resources.

Nevertheless, the progressive inclusion of economic criteria in national healthcare policies faces a number of hurdles. Price regulation, combining medical and economic assessment tools, takes place in a changing legal process, with the creation of agencies, usually independent from governments, and granted with varying mandates. The feedback from two or three decades of contrasted countries' experience shows that health technology assessment still does not play a full role in the allocation of healthcare resources. The inclusion of economic evaluation in drug price regulation has been part of a response to the challenge of increasingly high-cost treatments, but economic rationale through health technology assessment still has limited leverage on pricing decision (Franken et al. 2016). Yet, there is fast learning by doing, both for the healthcare institutions themselves and for their evaluation methods, due to the great challenges faced. In methodological terms, the quality of cost-effectiveness data appears as one of the most important stakes, along with the role of uncertainty surrounding efficiency outcomes in the price negotiation process. As for institutions, national regulatory agencies will increasingly have to find ways to conciliate country specificities with the necessity to provide joint and fast responses to the price claims of international firms.

Ecolables: Are they Environmental-Friendly?

Lisette Ibanez

LAMETA, CNRS, INRA, Montpellier SupAgro,
Université de Montpellier, Montpellier, France

Abstract

This article provides a general overview of the technical, economical, regulatory and environmental aspects of ecolabeling. An ecolabel is a market-based policy instrument that can be either voluntarily adopted or mandated by law. Ecolabels are applied to services and products in order to inform consumers of their environmental-friendliness and to avoid market failures. In reality, however, ecolabels do not always succeed in achieving environmental improvements. The mis-use of environmental standards, the practice of strategic manipulations that create trade-distortions, the excessive use of claims, and behavioural biases are some of the factors that can prevent an ecolabel from reaching its initial objective to reduce or even eliminate environmental externalities.

History

The phenomenon of ecolabeling had its beginning in the 1970s, driven by an increasing consumer willingness to pay for sustainable consumption.

Until that time, the management of environmental externalities relied mainly on the use of regulatory mechanisms that imposed requirements or restrictions on the operations of potentially polluting firms and entities.

The first official ecolabeling program, Blue Angel, was launched in Germany in 1977 and was followed by many other ecolabeling schemes in various countries and areas. Today, its development has permeated many sectors such as the food industry, cosmetics, home building, and even the automobile industry. After the 1992 UN Earth Summit conference in Rio, in which no world-wide agreement was reached for environmental protection, various initiatives (by governments, NGO's, private stakeholders, etc.) aimed to integrate environmental issues into manufacturing procedures. The idea was to influence consumption patterns in order to achieve sustainable development.

Since then, a burst of interest emerged for self-regulation and new environmental policy instruments, including ecolabeling, and an important change in manufacturing was observed in the United States: The percentage of new products claiming to be environmentally friendly rose from 1.1% in 1986 to 9.5% in 1999. Today, ecolabels are found everywhere: on a large variety of products and services, appearing on packaging, manufacturer's websites, or related to countries, or geographical areas. In total, 458 official ecolabeling schemes concerning 25 industry sectors have been reported in 195 countries

(Cf. <http://www.ecolabelindex.com/consulted> on October 2, 2014.). What's more, a great number of unofficial environmental claims are currently in use, as well.

Definition

Broadly speaking, ecolabels are claims related to environmental friendliness. They inform consumers about the environmental quality of products and services, enabling consumers to make better choices (Thøgersen et al. 2010). It is widely understood that people rely heavily on information provided by labels in making their consumption decisions. Nevertheless, the word ecolabel remains a fuzzy and ill-defined term that can encompass a variety of different meanings. It includes a diversity of environmental claims ranging from third-party certification schemes to self-declaratory statements. Thus, at one extreme, ecolabels are issued by independent organizations (and can be voluntarily adopted by firms), as for example, Forest or Marine Stewardship Council Certifications (FSC and MSC). At the other extreme, ecolabels can be simple marketing claims or logos related to some aspect of environmental friendliness and are often vague, undefined, unverified, and/or unverifiable. Examples of these types of ecolabels include statements on detergent boxes indicating that the product contains no phosphates, or a label on a washing machine claiming that it is energy efficient.

In general, the conceptual design of ecolabeling schemes includes four stages (Grolleau et al. 2007). The first stage involves the selection of product categories or services to which the ecolabel will apply. The second stage defines the criteria that the product, services, or production process must respect in order to be allowed to use the ecolabel. Both of these stages, i.e., choice of product categories and ecolabel criteria, may be established by governments, environmental organizations, consumer groups, industries, or some combination of these parties. The third stage concerns the inspection of the products and services according to the defined criteria. This stage establishes the methods by which eligible

products and services are to be tested and/or audited. The final stage develops the communication strategies or the way in which the environmental attributes will be signaled to the public.

Of course, the seriousness and accuracy of each of these stages vary highly according to types of environmental claims and labels and can therefore result in a wide range of compliance costs. In general, ecolabeling costs include the opportunity costs associated with efforts to conform to relevant standards (and thus testing and labeling) as well as the costs associated with efforts to create new markets. This means that firms must bear the costs of adjusting production processes in order to assure that products will earn the ecolabel, as well as the expenses of subscribing to and maintaining participation in these ecolabeling programs. Fees for these programs can be significant. Thus, under the assumption that firms are rational profit maximizers, their voluntary adoption of an ecolabel is conditional on the prospect of sufficient sales, higher prices, and due recognition of their environmental status by stakeholders and users.

Classification of Ecolabels

There are various ways of classifying ecolabels: they may be classified according to their legal status (mandatory or voluntary), the certifying entity (governmental, nongovernmental, or private rule-setting), the certification criteria (single or multiple criteria, product or process oriented, fixed or evolutionary mechanism), and even the geographical dimension of their production (regionally, nationally, or internationally defined).

In the interest of increasing the clarity and transparency of the ecolabeling process, the International Standard Organization has undertaken efforts to standardize ecolabeling principles. Specifically, it distinguishes between three types of environmental product labels, classified as ISO Type I, II, and III (Lathrop and Centner 1998). These three types of labels can be described as follows:

Type I (ISO 14024) labels are based on a set of criteria defined by private or public environmental

labeling programs and are issued and controlled by third-party certifiers. The awarding body may be either a governmental organization or a private noncommercial entity. Examples of such types of labels include the EU Ecolabel, the German Blue Angel, and the Program for the Endorsement of Forest Certification (PEFC). Type I labels are often referred to as ecolabels, despite the fact that they may coexist with other ecolabeling schemes (like the FSC program for example).

Type II labels are self-declared claims adopted by manufacturers, retailers, or anyone else likely to benefit from such claims. These claims can be factual (e.g., indicating the percentage of a product that is composed of recycled materials) or more unsubstantiated (e.g., simply “eco-friendly”).

Type III labels consist of quantitative product information based on life cycle impacts. In general, these types of labels consist of reports that are presented in a form that facilitates comparison between products, often using a common set of parameters. However, relative product performance based on these parameters is not provided in the label itself, as there are no comparative statements made with respect to other products. An example of Type III claims is the “carbon footprint.”

Despite their widespread use, relatively few regulations exist regarding the use of ecolabels on national levels. From a legal point of view, environmental claims are primarily seen as advertisements and less as market-based policy tools. As such, they are mainly regulated through antifraud and truth-in-advertising laws. However, the World Trade Organization (WTO) monitors the practice of ecolabeling in order to ensure that it doesn’t lead to discrimination between trading partners or between domestically produced goods and services and imports. In the case of disputed environmental claims, the WTO relies on rules such as the General Agreement on Tariffs and Trade (GATT) or the Agreement on Technical Barriers to Trade (TBT). More specifically, the WTO issued a Code of Good Practice for Preparation, Adoption, and Application of Standards to TBT Agreement in order to facilitate ecolabeling and standard setting in a manner that does not conflict with agreed upon

international trade frameworks. Often, it is very difficult to establish objective and scientifically defensible criteria that can justify or dispute claims of environmental superiority.

In cases where the voluntary involvement of an industry in an ecolabeling scheme is considered to be too low, governments may decide to oblige firms to undertake measures to reduce environmental impacts, adopt specific technology changes, or instate mandatory (national) labeling standards. For instance, in order to promote health, food, and environmental safety, governments may impose warning labels (e.g., for flammable materials, potentially dangerous household chemicals, alcoholic beverages, cigarettes). In these cases, producers who do not comply with the national standards cannot obtain access to markets within the country. For example, since 2010, EU Timber regulations prohibit the selling of illegally harvested timber and products derived from illegally harvested timber on the EU market. Trade barriers are not only enforced by laws, however, and can also result from consumer boycotts. Nevertheless, labeling requirements and practices must respect all the WTO regulations, including the provision of the TBT Agreement and the GATT. In other words, ecolabeling schemes should not discriminate either between trading countries and firms or between domestic and foreign products and services. There are several examples of debates regarding the legitimacy of ecolabels, due to the trade distortions arising from the enforcement of their environmental criteria. First, as stated by the OECD (2002) *“The experience of Colombian exporters of cut flowers to Germany provides an example of the impact which a powerful domestic NGO-driven voluntary eco-label can have on a developing country’s trade prospects (OECD 2002).”* This conflict originated with German NGO’s that campaigned against labor and environmental conditions in the flower export industry of developing countries. The Flower Label Program was created in 1996 and disputed by Colombian flower exporters who claimed that it created discrimination and unfair competition.

Another case in which pressure by local consumers and the media effectively excluded foreign

products from the domestic marketplace and created a conflict between international trade and domestic environmental law was the US/Mexico Tuna embargo dispute. In the 1990s, the US banned tuna imports that could not attest to being caught in a dolphin-safe way. The dolphin-safe label has legal status in the United States under the Dolphin Protection Consumer Information Act but was contested by Mexico as creating discrimination and illegal trade barriers (Dyck and Zingales 2002).

Principles of Ecolabeling

The rationale behind ecolabeling is to overcome the market failures that arise in marketing eco-friendly products and services. Markets for environmentally friendly products and services are dysfunctional because most of the promised environmental attributes are both public (nonrival and nonexclusive) and unobservable (credence attributes).

Neoclassical economic theory predicts that consumers will attempt to freeride by enjoying a public good (environmental quality) without incurring the costs associated with its provision. This means that if ecolabeled products are more expensive, there should be no market for them. However, in the last decades, consumers have increasingly considered not only their own well-being but also the environmental and social impacts of their purchasing decisions (Cohen and Viscusi 2012). Motivations for adopting socially appropriate behavior can be explained by preexisting personal norms or by emerging social norms. Nevertheless, even if it has largely been shown that consumers possess other-regarding preferences and are willing to pay for environmental attributes, another requisite for firms to invest in environmentally friendly production technologies and to offer less polluting products and services is the opportunity to provide credible information to users and consumers.

In order to determine the value that consumers attribute to an ecolabel, it is important to distinguish consumer understanding of the ecolabel, consumer confidence in the ecolabel, and their

willingness to pay for environmental amenities (Delmas et al. 2013).

In the literature, it has been shown that simple eco seal type labels are insufficiently convincing. Adding additional information about specific criteria that are defined and verified by a certification scheme can significantly increase willingness to pay (O'Brien and Teisl 2004). Ecolabels have also been found to perform better if the certifier is a familiar organization and/or endorsed by an independent third party (D'Souza et al. 2007), without ignoring that the success of the ecolabeling scheme is also determined by the individual characteristics of the purchaser (Teisl et al. 2008). Moreover, consumers are willing to pay higher premiums for ecolabels where the benefits of environmental improvement are also linked with private benefits. For instance, organic farmers strive to make their food products more appealing by stressing not only the reduced environmental impact of using less pesticides but also by emphasizing the accompanying reduced health risks.

Under the assumption that ecolabeling schemes have the ability to correct informational asymmetry within the producer-consumer relationship, firms are generally motivated to adopt ecolabels in order to differentiate their products. As pointed out by Porter (1991), (environmental) competitive advantages are obtained either by lower costs or by attribute differentiation. In many cases, new technologies with lower environmental impacts are not associated with lower costs; thus, a firm's primary interest in using ecolabels is founded in a search for strategic environmental competition. In developing a strategic advantage based on environmental quality attributes, firms can either focus on their internal organizational process or on their product line. Globally, differentiation will be based on creating a positive image, pursuing positive recognition by stakeholders, or the anticipation that more stringent environmental standards may be implemented in the future.

Voluntary label adoption as a differentiation strategy will affect competition, as it enables products to be perceived as imperfect substitutes (Bonroy and Constantatos 2015). In addition,

ecolabel adoption only partly corrects market failures relating to environmental degradation (Ibanez and Grolleau 2008). The incentives for firms to turn to new environmentally friendly standards and to adopt ecolabeling depend on several factors that can be classified into three general categories: factors relating to market structure and governance, willingness to internalize environmental externalities, and the ability of ecolabels to accurately communicate the certification criteria.

Firstly, there are factors related to the market structure and to the involvement, number, and type of policy makers. Firms' incentives to ecolabel are highly dependent on the costs of investing in green technologies, which concern both fixed (sunk) and relative unit costs, and on the ability of ecolabeling to release price competition. The inherent aim of the investment decisions made by firms is to consider how to best adapt their technology to standard requirements and do not necessarily aim at socially optimal outcomes in terms of environmental improvements (Amacher et al. 2004). Ecolabeling programs differ crucially from standard requirements in their ultimate goal. If an NGO initiates an ecolabeling program, it may likely set standards that maximize environmental improvements, whereas an industry-initiated ecolabeling program may instead be oriented by the pursuit of maximizing industry profits. Consequently, one would expect ENGO's to set more stringent standards than industry-sponsored ecolabeling schemes. It should be noted that more stringent environmental requirements do not necessarily lead to better global outcomes in terms of environmental degradation due to restricted use and consumption (Grolleau et al. 2009). Certifying entities may also compete to capture a firm's willing to adopt an ecolabel, strategically choosing their qualifying criteria in order to maintain their market share of participating firms. The coexistence of both NGO and industry ecolabels should theoretically favor industry profits, since environmental improvement is only feasible if the reduction in "high-environmental quality" labels doesn't outweigh the increase of overall ecolabel users (Fischer and Lyon 2014). Governmental involvement also

plays a role in firms' willingness to adopt ecolabels and thus the overall effectiveness of ecolabels as an environmental policy strategy. In some cases, a market-based ecolabeling mechanism may be reinforced by complementary policy instruments in order to internalize externalities more efficiently (Nunes and Riyanto 2005). These complementary regulatory policies can either be mandatory (e.g., minimum environmental quality standards) or voluntary (e.g., subsidies for green investment).

A second determinant that explains the emergence of ecolabels concerns consumer willingness to pay for the reduced environmental impacts of products and services. The inclusion of social and environmental considerations in consumer decision-making processes has become more common in the last decades, and globally it has been shown that there exists a willingness to pay for social and environmental attributes. However, disagreements remain regarding the price premiums of these attributes (McCluskey and Loureiro 2003). This variation in estimated willingness to pay (WTP) observed in the literature can be attributed to the elicitation methodology used (based on either stated or revealed preferences) but can also, and is most often, structurally based. Indeed, ecolabeling may suit certain products better than others. As an illustration, if consumers value ecolabels for conspicuous reasons, it is important that the ecoseal and the associated product are seen by others. If warm-glow motivations are an important driver of behavior, then consumption of goods with symbolic logos (e.g., dolphin-safe fish, panda bear logo of WWF) may benefit from higher premiums. Thus, the design of an ecolabeling scheme and the associated communication strategy should consider the specific motivations underlying the demand for social and environmental attributes.

Lastly, the salience and efficiency of ecolabeling schemes rely on factors related to the ability of ecolabels to provide information on environmental attributes perfectly and symmetrically. Mason (2011) argues that incentives for firms to apply for ecolabels depend on the ability of third-party certification schemes to accurately distinguish high-environmental quality producers from low-environmental quality ones. Imperfect

label attribution arises either because monitoring is random or because the auditor is incapable of accurately identifying compliance with the required standards at a reasonable cost. This “noise” in testing procedures may even encourage less environmentally sensitive firms to apply for certification, which lowers consumer expectations of environmental quality in all similarly labeled products. Moreover, trust in an ecolabel is reinforced when the label is provided by independent and well-recognized certifying agencies (D’Souza et al. 2007) and if the entity has no financial interest in providing the certification (Harbaugh et al. 2011). In addition, the degree of consumer uncertainty regarding ecolabel claims rises along with increased market proliferation of these types of claims, as consumers will have more difficulty interpreting the absence or presence of an ecolabel, and consequently willingness to pay will decrease.

Efficiency of Ecolabels: Positive and Negative Side Effects

From a theoretical point of view, the introduction of ecolabels should be welfare enhancing as it provides information on the environmental attributes of products or services for which consumers are willing to pay, enabling simultaneous environmental improvements (Ibanez and Grolleau 2008). However, market-based policies and information disclosure, even if they are well known to minimize market distortions, may also result in unintended side effects. Indeed, the misuse of environmental standards, strategic manipulation that creates trade distortions, the excessive use of claims in general, and behavioral biases are some factors that might prevent an ecolabel from reaching its initial objective to reduce or even eliminate environmental externalities.

The motivations for introducing ecolabels and the process of defining and choosing standards are not necessarily the same among environmental organizations, governments, and industrial-oriented entities. While environmentalists focus on criteria that lead to the greatest environmental improvements, industries aim to set standards on

product categories and/or criteria that involve the lowest costs and to take advantage of positive spillover effects such as an improved reputation among consumers and/or an increase in sales of other product categories (Dosi and Moretto 2001). Then, in some cases, the consequence of ecolabel introduction may in fact turn out to be globally harmful for the environment. In these cases, the environmental gains achieved are inferior to accompanying increases in product consumption and resulting pollution.

However, nonprofit labeling schemes do not always eliminate inefficiencies either. Potential examples include technological inertia in the form of reluctance to accept innovative technology developments, imposing excessively stringent standards or costly monitoring processes, and failing to gain sufficient recognition by consumers.

Moreover, the choice of labeling criteria can potentially be used for protectionist purposes. For example, industrialists may select environmental considerations that both meet environmentalists’ concerns and disadvantage rivals. An intuitive example can be found in the environmental impacts of transportation. Domestic firms may overemphasize the role of certain transportation means (e.g., air transport vs. rail transport) in order to discredit foreign rivals. Differences in environmental issues among countries may also be employed in order to disadvantage foreign producers. Furthermore, for variety of reasons – e.g., political support, ideological protectionism – domestic governments may be more sensitive to arguments emanating from domestic producers and environmental activists, regardless of their scientific validity.

Harmonizing ecolabel standards on an international level seems to be a difficult task. Institutional, technological, and environmental heterogeneity between manufacturers is likely to favor strategies that seek to raise rivals’ costs. In other cases, entities may focus on local or regional environmental priorities that lack international relevance and/or create trade barriers.

In general, developing countries are more vulnerable to the discriminatory impacts that can arise with ecolabeling schemes. First, it is more

difficult for these countries to bear the costs of the certification procedures required for the compliance, testing, and verification of the labeling criteria. Second, developing countries often lack information on requirements and do not have access to the necessary skills and technologies that would allow them to conform to domestic standards.

The proliferation of ecolabels also raises important questions. Theoretically, providing information on products and services should enable consumers to update their beliefs, thus having a positive impact on environmentally friendly consumption decisions. However, the proliferation of ecolabels today has, in some cases, led to an excess of information that users must process, contributing to increasing consumer confusion, indifference, and even skepticism towards ecolabeling schemes.

The overuse of environmental claims by firms may also be viewed as greenwashing by consumers. Consequently, there seems to be a need for more efficient auditing of the various stages of the ecolabeling process (Lyon and Maxwell 2011). But such regulatory intervention is costly, often imperfect, and not necessarily legally binding. Today, no binding legal framework at the international level exists in order to ensure the reliability of green claims, i.e., in order to verify whether the relevant labeling criteria are respected as defined by ISO 14021. To fill this gap and to call for a legal framework, private initiatives have denounced firms that use “misleading” and/or inaccurate advertising regarding their actions in favor of the environment. In 2008, several environmental NGO’s decided to attribute an award, called the Pinocchio prize, to firms who promoted themselves to be greener than they actually are (<http://www.prix-pinocchio.org/>).

In order for ecolabels to be effective, consumers must receive, process, and believe the information transmitted by labels. Therefore, the type and the content of information transmitted by ecolabels are of crucial importance. The aim of an efficient label design is to provide consumers with information that increases understanding of environmental targets and improvements in a credible manner and may simultaneously boost

pro-environmentally friendly preferences themselves (Delmas et al. (2013)).

Truthful ecolabels do not necessarily achieve environmental policy goals. Because consumers tend to focus only on the emphasized attribute, they often underestimate the overall environmental harm resulting from their consumption and use of the product. For instance, by buying fluorescent light bulbs, consumers may focus on the energy saving properties yet underestimate the environmental damages that result from the emission of mercury vapor occurring when these lights are disposed. A great many other behavioral biases may also distort the efficiency of ecolabeling schemes (Grolleau et al. 2015). For example, people in general overestimate their own virtuous behavior (optimism bias) and underestimate the degree to which they are implicated in contributing to negative externalities (attribution error). If these cognitive biases apply to ecolabeled products, people may allow themselves to increase consumption of environmentally friendly products thinking that their consumption is less harmful, while in reality their increased consumption may in fact contribute to a net deterioration of the environment (Bougherara et al. 2005).

An important determinant in consumer behavior is other-regarding and social preferences. And one can imagine the progressive shift of markets towards more sustainable production and ecolabeling may have the potential to increase consumer preferences for environmental-friendly attributes in the long run. In other words, exposure to an increasing and diverse range of ecolabels can trigger new social norms pertaining to acceptable environmental behavior.

However, even if exposure to green products may activate norms of social responsibility and ethical conduct, it may also give rise to a rebound effect (Cohen and Viscusi 2012). Recent research has shown that green consumption or pro-environmental conduct can modify people’s overall sense of morality and affect subsequent behavior either within or outside of the concerned domain (Clot et al. 2014). This moral compensation, also called the “licensing effect,” shows that doing something virtuous seems to give individuals license to later engage in more immoral

actions. The consequences of this phenomenon can be diverse and have negative impacts on the global environment through the reduction of pro-environmental behavior in subsequent decisions or in other domains.

Conclusion

In theory, ecolabeling is an efficient way of regulating environmental externalities, under the condition that the additional costs don't exceed consumer willingness to pay for environmental quality. When this is the case, voluntary approaches for environmental regulation are good alternatives to command and control policies. However, in real life, ecolabeling does not always achieve its initial goal of environmental improvements due to a variety of side effects. Intervention or regulation could then provide a way to correct these inefficiencies (Horne 2010).

But what should be the role of governments? Is new legislation the only way to regulate inefficiencies, or can efficient voluntary mechanisms be implemented to effectively encourage optimal behavior? It is important to be able to measure the global effectiveness of ecolabeling programs through assessments on an international level. The importance of environmental improvements in relation to trade distortion raises ethical and equity issues and calls for better insights on the economic implications of the interaction between ecolabeling schemes and (already existing) command and control policies.

Regarding the extent to which ecolabeling should be regulated, a distinction should be made between interventions in the certification process and scheme, and interventions regarding the use of ecolabels as a communication tool. A first task is thus determining which products and services should be targeted to use ecolabels. One might wonder whether consumers should systematically be encouraged to purchase ecolabeled products and services and firms pushed to adopt ecolabels and more sustainable production technologies. Complementary policies on both the national and international level should also target ecolabels. Nevertheless, the simple

provision of accurate product information is often not enough to induce behavior change, and thus social and behavioral research could help policymakers to better design ecolabels in order to improve their overall effectiveness (Grolleau et al. 2015). One promising new strategy emphasizes the importance of educating the youngest generations in environmental issues and the relevance of ecolabels to these issues.

Economic Analysis of Brazilian Labor Law

Sergio Pinheiro Firpo and Luciana Yeung
Insper Institute of Education and Research,
São Paulo, Brazil

Definition

Being a civil law country, Brazil heavily relies on codified rules to regulate labor relations. For this purpose, back in the 1940s,

a comprehensive set of laws was consolidated in the *Consolidação das Leis Trabalhista* (CLT), which remains the main source of labor regulation in the country, even after some minor reforms in the end of the year 2017 (to be discussed ahead). Besides the CLT, the Federal Constitution itself has several clauses governing labor and employment relations. Finally, more and more judicial precedents have been taken and followed (although not in a mandatory manner) as sources of law.

Introduction

Labor law in Brazil is based on a paternalistic, overly protective, and dictatorial view of employees. The first and perhaps most important principle is that of the vulnerability of employees: these are considered almost legally incapacitated, with no knowledge whatsoever of what their desires are. This is the first and sharp contrast with the economic concept of rational agents: people do know what their preferences are and what costs they must incur in order to maximize their benefits.

Another assumption by the Brazilian labor law is that of adversarial relations between employers and employees. On one hand, employees are considered to be irrational, not knowing what their preferences are, and totally lacking bargaining power; on the other hand, employers are considered to be pure profit maximizers, willing to adopt inhumane conditions for his/her employees with the sole objective to reduce production costs. Because of that, legislators, judges, and law enforcers will stay vigilant to regulate this relationship. Under such circumstances, the scenario predicted by Coase, of cooperative bargaining, leading to efficient allocation of resources, becomes even more a piece of fiction. Labor relations, by definition and assumption, are considered to be of very high transaction costs. Then, as Coase's theorem clearly predicts, the law will directly impact on the efficient allocation of resources. The question is as follows: Has this impact been mostly positive or mostly negative in Brazil? The answer is not difficult to find. We provide in the second half of this

entry a brief review of the empirical literature showing the negative impacts on efficiency of these regulations.

Main Characteristics of Labor Law and Labor Justice in Brazil

Conflicts are pervasive in judicial relations in Brazil. The judiciary power is comprised of five big branches: Federal justice (for all matters related to the Federal Constitution), common state justice (for most civil cases, such as commercial, tort, family, consumer rights, etc.), military justice (for trials involving the military), electoral justice (running the electoral system), and labor justice. Within it, a three-tier structure exists, comprising local first-instance courts, second-degree regional courts, and a supreme labor court. In cases where labor conflicts involve constitutional matters, cases and appeals may be directed to Federal courts, even the highest Federal Supreme Court (STF).

Given such a structure, it is not a surprise that this is a highly conflictive branch of law. Official statistics published by the National Council of Justice (CNJ) – the “Justice in Numbers” (*Justiça em Números*) reports – testify this: in 2016, there were 1721 new cases in labor courts for every 100,000 people, or a total of 4.3 million new cases. With regard to pending cases, labor courts comprised 5.4 million, placed top 3 (6.8% of total), behind only to state courts and Federal courts. As a specialized branch of the judiciary, labor courts have far more cases than those of the electoral justice, which in 2016 received only 972,000 new cases.

Furthermore, “Justice in Numbers” also shows that the most frequent theme in all Brazilian courts, the top 1 subject of judicial conflicts, is “labor dismissal/dismissal fees,” comprising 11.5% of all cases brought to courts in Brazil. In 2016, they represented more than 5.8 million cases. Top 2 conflictive subject was “breach of contracts” (not including labor contracts), with far less, 1.9 million cases.

One can affirm, with certainty, that labor laws are not bringing harmony in employers-

employee’s relations, or in Coasean terms, the law is not reducing transaction costs.

Historical Background: The Creation of Labor Laws and Labor Justice in Brazil

Labor law and labor justice were born under a dictatorial regime in Brazil. The first compilation of labor laws, the *Consolidação das Leis Trabalhistas* (CLT), was made in 1943, 2 years after the birth of labor courts in the country. Both are creations of populist dictator, Getúlio Vargas. In his turn, Vargas came to power with the 1930 revolution, which put an end in the “old republic” in Brazil, which had been dominated by the rural coffee aristocracy. Vargas’ regime represented the beginning of the political power exerted by urban industrialists and bourgeoisie. His government was one of the extreme instabilities, pointed by several attempts of coup and a few effective ones, ending in a dramatic way, with the suicide of Vargas in 1954. He took power twice, in a total of 18.5 years (1930–1945 and, then, 1951–1954). It was during his first government, under a dictatorship, that labor law was created. It is usually considered to be a populist dictatorship, commonly observed in several Latin American countries at that historic time.

Those were years of intense social transformations in Brazil: industrialism, urbanization, and influx of foreign immigrants. In order to maintain social order, Vargas managed to control the various classes that were emerging, especially urban groups. Being a founding member of the “Brazilian Labor Party” (*Partido Trabalhista Brasileiro*, PTB), he had strong commitment with the labor class. Another important historical event from those years was the emergence of communist ideas, mainly brought by the Italian immigrants. In response to all these movements, the creation of the labor justice and of labor laws was a means to pacify and monitor potential labor movements adversarial to the government. The paternalistic approach adopted by this legal structure was a manner to compensate the

intense monitoring by the government that the new system established.

According to Lopez (1991), the unification of all previous labor laws under the CLT represented a “combination of state paternalism and fascism, which was the essence [of Vargas’ dictatorship]” (free translation). Some characteristics of the Brazilian labor structure reveal the accuracy of this analysis. Vargas created a “fake” unionism, which included monopoly of representation, i.e., only one union per professional category in a particular geographical region. Employees must pay compulsory union fees (deducted from their paychecks once a year). In turn, unionism is funded by public resources. Unsurprisingly, unions were mostly subordinated to the Federal government. By its turn, labor laws, greatly represented by the CLT, impose high financial costs and responsibility burden on employers. Legal rules are generally applied under the rule of strict liability (Yeung 2006). Labor law is based on the principle of vulnerability of the employee, under all circumstances. This means labor conflicts will never be solved as contractual conflicts by Brazilian courts. There is a long list of labor benefits that employers are mandated to provide. This, in turn, increases labor expenses up to 200% of what employees effectively receive as paycheck (Pastore 2007).

Paternalism toward employees is also reflected in procedural rules. Until a very recent reform in labor laws, employees had no costs at all to access labor courts: all that was required was a self-declaration of financial incapacity. This certification was, then, later submitted for approval by the judge. Decisions were made based on the judge’s subjective opinion; there was no requirement for financial statements. This procedural rule was granted by a combination of principles present in Brazilian labor laws, a rule issued in 1983 (Law Number 7115) and several labor jurisprudence. Furthermore, although provided by procedural law, “*bath faith litigation*,” or litigation without reasonable motif, is rarely punished in labor courts. With all this in place, it is not difficult to understand why there is so much conflict in Brazilian Labor Justice.

Distortionary Effects of Labor Law in the Brazilian Labor Market

There are three important features of labor law in Brazil that, in spite of being the source of several distortions in the labor market, they were not affected by the 2017 reform, which we shall discuss in the next section. These three aspects are *firing costs*, *labor taxes*, and the existence of the Brazilian Severance Indemnity Fund, known as *FGTS* (Fundo de Garantia do Tempo de Serviço). These three components have had important effects on the labor market over the past decades affecting employment levels, unemployment and informality rates, and labor productivity.

Firing (or dismissal) costs are the set of rules in labor law that cause the firm-employee separation, whose initiative is by the employer, to involve some pecuniary penalty to the firm, both by means of indemnification to the dismissed worker and by means of fines paid to the government, in addition to prior notice to the worker. Firing costs in Brazil are relatively high, as they involve a fine of 40–50% of a monthly salary for each year in the firm, plus 1 month as prior notice to the worker, who may not need to fully work during that period. Higher dismissal costs induce lower job variability and a lower level of formal employment because firms tend to hire less, since any reversals in product demand could lead to costly layoffs in the future. The effects on informality are the opposite, and higher dismissal costs induce higher levels of informality. Finally, because (i) dismissal costs have a reallocation effect from formal to the informal sector and (ii) the latter has an average productivity below that of the formal sector, the higher the firing costs, the lower the labor productivity. In addition to that effect, there is the productivity-reducing effect in the formal sector, because firms in that sector will typically operate below the optimal labor demand curve.

Labor or payroll taxes are those that are paid when hiring an employee. There are many taxes and charges on payroll in Brazil, and they may vary between 20% and 50% of overall labor costs. These taxes are, in general, proportional to the time of service and to the salary paid. The effect of levying labor taxes is well known and amounts to the

reduction of employment. These taxes shift the labor supply curve inward and upward, and therefore their effects on unemployment and informality are inversely proportional to what they have on employment. Finally, labor taxes reduce the marginal productivity of labor for two reasons. First, after an increase in labor taxes, workers who will remain employed are those in the points along the supply curve that are associated with lower reservation wages. Because reservation wages reflect productivity, average labor productivity will decrease after an increase in labor taxes. The second reason is related to the increase in informal sector induced by these taxes, which tends to operate under lesser conditions of productivity.

The last important feature of the Brazilian labor law that has not been affected by the recent reforms is FGTS, the Brazilian Severance Indemnity Fund, which was created in 1966. From the 1940s until 1966, Brazilian labor law stipulated that in the case of unjustified dismissals, firms should pay as compensation to the worker one monthly salary for each year worked at the firm. In addition, the law guaranteed job stability for workers who had an employment spell longer than 10 years with the same firm. FGTS was introduced with the aim to introduce flexibility in the job relations. Since 1966, workers have not had job stability. But they have kept access to the one monthly salary for each year worked at the firm. That amount is deposited by the firm into an individual FGTS account. Workers also are eligible to a 40% fine over the balance in the case of unjustified dismissals that is paid by the firm at the time of dismissal. Thus, FGTS is not a simple labor payroll tax: it is a mandatory savings account paid by the employer plus a fine that is appropriated by the worker. That account can only be accessed if the worker is fired. Voluntary dismissals do not allow withdraws from the FGTS account. Therefore, FGTS induces the opportunistic behavior of workers who always benefit from being fired: they may have granted access to their FGTS account and to the fine. Because the interest rates accruing FGTS accounts are lower than inflation, it is rational for workers to try to have access to their individual accounts. The overall effects of FGTS are excessive labor turnover, which reduces labor productivity. Since it increases

labor costs for the firms, it also has all those other effects already described for labor taxes: lower employment, higher unemployment, and informality rates.

Labor Law and Labor Courts After the 2017 Reform: An Economic Analysis

In November 2017, a so-called labor law reform took place in Brazil, 74 years after the creation of the CLT, which remained basically untouched during all this time. In fact, it was approved by the National Congress in July, under Law N. 13,467, in a very heated process, severely opposed by trade unions and labor movements. The law in its integrity has close to 900 articles. For the purposes of this paper, we highlight three very important ones. We then provide a brief economic analysis of these topics (Yeung 2017).

1. (Articles 611-A and 611-B) Individual and/or collective agreements gained much importance as compared to legally issued laws over the discussion of a wide variety of themes. For a civil law country, highly dependent on legislative rules, this was a significant change in the process of creation of formal rules for labor relations.

Economic analysis: This is one of the most controversial points of the 2017 labor reform. However, it is very much in line with an economic analysis of labor, especially under the concept of rational agents and of the Coase theorem: employees know what is good for them and, when bargaining conditions are guaranteed and transaction costs kept in low levels, the result of the cooperative bargaining between employees and employers will be efficient. This is especially true if negotiation occurs with the support of labor committees or labor representatives at the workplace (as predicted by Article 510-A). Furthermore, although Article 611-A predicts 15 matters over which cooperative agreements and private bargaining can stipulate, Article 611-B lists 30 matters (i.e., double the previous number) which there must be *no* private negotiation, over

which only the law may regulate. These are mostly laws related to situations in which negative externalities are created by the employer to the employees and to the society.

2. (Articles 545, 578, and 579) Employees are no more legally required to make contributions to trade unions: the rule that mandated each employee to make an annual contribution equivalent to the wage of 1 day of labor, stipulated by Getúlio Vargas, is finally banned. Now, in order to get the contribution, unions must have written consent by the employee (but the rule of monopolist trade unions was unchanged).

Economic analysis: The former rule mandating union contribution by each formal employee was a clear violation of the freedom of association, especially in the case of Brazil, where there exist monopolist trade unions. That law could only have been created under a dictatorial political regime. Economic analysis would go beyond in the normative recommendations and demand for the extinction of union monopoly.

3. (Art. 791-A) Sums of surrender are owed by the employee, in cases of judicial defeat. Curiously, this rule has normally been applied to all other civil cases, even those with legally vulnerable parties, such as consumers against enterprises. The only exception happened in labor courts, and now, with the 2017 reform, this exceptionality has also gone away.

Economic analysis: If employees have “nothing to lose” when accessing labor courts, certainly they will access. This is one main reason of the statistics with evidence of over litigation in the labor justice, as seen before. Another reason might be a potential bias pro-employee and anti-employer by labor courts. The combination of these two factors leads to the very adversarial relationships between the two parties. With the end of the gratuity to access labor courts, it is expected that there will also be a reduction in the numbers of labor litigation.

Few months after its real implementation, some anecdotal evidence show the 2017 labor

reform has already produced concrete impacts on courts, by significantly diminishing the number of labor cases filed. We believe it is still early to significantly draw such conclusion. Hopefully, future academic research will address whether this small step was able to significantly improve the environment of labor relations in the country.

Economic Analysis of Labor Law

Luciana Yeung

Insper Institute of Education and Research, São Paulo, Brazil

Abstract

The literature on labor relations has been very much divided, mainly between the classical economic approach and the legal/sociological

one. An economic analysis of labor law would benefit by abridging both perspectives and complementing with more. This entry provides brief comments of why whether a purely economic approach on labor or a purely legal approach based on capital vs. labor dichotomy is not sufficient to properly address the subject. Several topics related to labor regulation are discussed, and empirical references on those issues are provided.

Economic Analysis of Labor Law and Labor Relations

Since the beginning of humankind, labor was exercised for people's needs. The study of human labor, its relation with the environment and its impacts in human relations within groups, is possibly one of the oldest social studies. Since the Greek philosophers and the Medieval religious scholars, up to the modern and contemporary economists, social scientists, psychologists, industrial engineers – just to name a few – several brilliant minds have engaged their time and research to understand the phenomenon of human, either in a positive or a normative manner. Many of the classical titles in economics and sociology were inquiries on topics related to the nature and consequences of human labor, such as Karl Marx's *The Capital*, Max Weber's *The Protestant Ethic and the Spirit of Capitalism*, and, in some sense, Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations*.

However, in recent times, the study of labor has been absolutely divided. On one side, economics – and specifically labor economics – has been mainly concerned about players' benefits. The economic approach is concerned with the analysis of workers' jobs, income and benefits (short term and long term), pension, etc. For the employers' side, economic models have studied impacts on productivity, profits, flexibility, etc. This perspective sees workers and employers as if the only things these actors pursue in the labor arena are economic and material benefits and that the main relationship here is of sellers and buyers. This is the basic framework of labor economics:

a market in which demand (workers) and supply (employers) interact.

On the other side, there is a wide range of scholars analyzing labor relations (until very recently also known as industrial relations) in a very different perspective. This group includes labor sociologists, labor lawyers, and labor historians – among others, who do not view employers and workers as merely in a seller vs. buyer relationship; instead, these researchers see a naturally antagonistic relationship at the labor *arena*. The model of capital vs. labor is the axis of this analysis, and all outcomes derive from it. Especially in the case of labor law, it aims at deriving rules that would smoothen this conflict (whenever possible) or that would balance the opposing forces, normally by protecting the weakest part, i.e., workers. These scholars consider the *locus* of labor as a battlefield, in which conflictive relations pervade, as if confronting with each other was the only thing that matters to these actors in their daily encounters at the workplace.

Needless to say, both approaches are limited and insufficient.

An economic analysis of labor law should take both sides of the view and complement with more. It incorporates features of the demand-supply model of labor and especially recognizes that workers and employers equally face several kinds of *incentives* and *constraints*, which affect their decision-making. However, it also gives significant importance to the formulation, application, and enforcement of rules, whether contractual or regulative ones, in the labor arena. It recognizes that the relationship between employers and workers is not a mere one of seller vs. buyer, or supplier vs. enterprise, and that labor is not a simple commodity. Human relations and power relations matter much here.

Although economic analysis of law a priori adopts the main economic framework, which considers labor *locus* a market, it recognizes that this is a special one, in which failures are the norm: asymmetric information (either from the employer to the worker or from the worker to the employer), externalities, uneven bargaining and political powers, monopoly, and monopsony,

among others. Externalities are sources of high transaction costs, and as the normative approach of the Coase Theorem tells us, under these circumstances, legal rules have an important role in the determination of the levels of efficiency (Coase 1960; Cooter and Ulen 2007). In other words, in this market, institutions matter and matter a lot.

Special Rules for a Special Market

Market failures exist in all markets. Yet, in the context of labor, they are essential features, not exceptions.

Asymmetric Information

Whenever labor is done for others – i.e., not for one's own subsistence – it entails a contractual relation, either a formal or an informal one. It is a contract because it is a *promise* made by someone to deliver something in exchange of another thing, and this is an enforceable promise. Workers promise to work under such and such conditions, to deliver certain tasks and/or to obtain certain results, in exchange of salary and a certain set of benefits. Employers, in their turn, promise to provide certain working conditions in exchange of workers' labor, which is used to produce goods and services, which, in turn, generate receipts and profits. The presence or absence of a written paper does not alter the fact that this relationship has a contractual nature, because both formal and informal contracts have their valid mechanisms of enforcement; it does not mean that written contracts are less effective in the guarantee of productive outcomes. The comparison between formal and informal types of contract is not the main issue of this brief entry, and, for our purposes, one should only bear in mind that labor entails, indeed, a contractual relation.

Besides that, most of the transactions between employers and employees are non-instantaneous, long-term interactions. The longer the relationship, the stronger are the impacts of uncertainties. For instances, neither the employer nor the employee knows, at the time of the recruitment, whether the economy will be booming or will be slowing down

in the following years (which may impact in the employer's ability to pay higher salaries); both parties do not even know how long will the company survive in the market.

Finally, human interactions are characterized by imperfect and unbalanced information: one is never able to access the whole set of information related to the other party, due to limited cognitive capability and due to high transaction costs. This is true even for noneconomic human relationships such as marriage, friendship, etc. In the case of employers, even if they try hard to access candidates' true ability (even by means of sophisticated processes of screening), they will not be able to fully acknowledge the candidate's adequacy for the position. Employers will also not be able to access the candidate's real interests in joining their firm ("Does this candidate plan to stay here long? Or will she/he leave the company as soon as another opportunity appears in the rival company?"). On the employee's side, she/he, at the time of the recruitment, is not able to fully access the challenges of the new job (even if one seeks information with current employees); she/he might not be able to understand the easiness or difficulty to interact with the new boss. Not even is the candidate able to access vital information about the company's finances and organizational challenges.

Externalities and Interdependence of Utility Functions

Employers depend on workers to reach some of their desired outcomes; workers, on their side, depend on employers to reach their economic benefits. This is what economist calls an *interdependence* of their utility functions. Whenever it happens, negative externalities might be created: one's decisions or actions might inflict undesired costs to the other party.

However, positive externalities might also be created. In the labor context, whenever an employer decides to train or educate his/her workers, he/she creates benefits not only for the company, for the trained workers, but potentially to the whole society, since a highly skilled labor force generates technology and knowledge that may benefit the whole society, directly or

indirectly. This is true both for general and for firm-specific skills. The same happens when employers invest in workers' health and safety conditions and so on. Thus, giving incentives for employers to invest in his/her employees' well-being also generates social efficiency. Yet, one knows from economic models that externalities – both negative and positive – drive the economy away from the point of efficiency: in the presence of *negative* externalities, private parties tend to provide *excessive* amounts of products and services; on the other hand, *positive* externalities lead to *insufficient* amounts. In both cases, regulation is necessary to guarantee efficiency: for negative externalities, taxes and quotas must be stipulated; for positive externalities, public policies must provide subsidies or other incentives to stimulate their production.

Uneven Bargaining and Political Powers

Economists are unable to deal with the concept of power relations. This is a phenomenon that cannot be explained by economic rules nor economic models. Yet, they significantly affect bargaining outcomes, even in the context of Coasean bargaining, with impacts on efficiency (e.g., Galiani et al. 2014; Barnes 2004, among others). It is also unrealistically naïve to consider this market as having “normal” supply and demand forces, with equal bargaining power. For most systems, employer and employees – especially if these ones are treated individually – do *not* have equal stands in the negotiation of working conditions. Thus, to assume that this is an ordinary contract relationship, in which clauses are outcomes of cooperative and voluntary agreement, does not truly mirror reality. Sociological, cultural, and political variables may explain why workers' bargaining powers are, on average, stronger in one system than they are in others, but the common-law tradition which views labor regulation as another ordinary type of contract regulation might not be well suited for other countries; probably, there are places in which power imbalance between workers and employers is larger. Then, other types of labor rules must be considered, so to take the “power effect” into consideration.

Monopoly-Monopsony

The historical answer to uneven bargaining and political powers in labor relations was labor organizations, mostly (but not exclusively) trade unions. Yet, this creates a problem of another sort: unions operate, most of the time, as monopolies in the labor market. As one knows, monopolies create deadweight loss: due to the existence of unions, wages tend to be higher, and as a response, employers are willing to hire less labor. In addition to that, because membership is never mandatory, the presence of unions creates an even worse outcome, dual labor markets, in which unionized workers have higher benefits but at the cost of nonunionized ones. In poor countries, this is materialized, in its extreme, into the case of formal vs. informal labor markets, with a large portion of the labor force belonging to the second one. Needless to say, working and living conditions here are strikingly adverse. We will discuss some empirical findings about trade unions in a specific section ahead.

It is also not unusual to find cases of monopsony in labor markets: one or a few firms are the sole employers of a certain type of workers in a region. Under these circumstances, employers have abnormal market power to unilaterally set wages, working conditions, etc., to which workers have little chances to react. A monopsony may be as damaging for social welfare as monopolies.

Litwinski (2001) discusses both problems in the labor market and, within the American context, defends the application of antitrust law to unions (as it has happened in the USA since the beginning of the twentieth century, in the *Loewe vs. Lawlor* case in 1908) and of labor and antitrust laws to firms, whenever they operate as labor monopsonies. Further, he claims that “anti-trust law and labor law are somewhat like Siamese twins unhappily separated at birth. The natural affinity between their subject matter and concern was recognized by the early cases and statutes” (p. 50). According to the author, in the same manner that labor unions should be prohibited to exercise their monopoly power, firms should also be disciplined in their monopsony power.

Labor Laws for the Labor Market

Summing up, labor relations are based on contractual, (usually) long-term relationships, characterized by high levels of uncertainties and asymmetric information. Different to what happens in some other markets, bargaining power here is inherently uneven between suppliers (i.e., workers) and demanders (i.e., employers), and monopolies and monopsonies occur frequently. Besides that, workers' and employers' utility functions are interdependent. All this shows that market failures are abundant in this case. As economic theory tells us, regulation is needed to solve these failures. A third party – usually the government – must step in; otherwise, efficiency will not be achieved, and maximum welfare will be missed.

However, bad regulation might be worse than no regulation, and many times, the problem lays here.

The Dilemma of Labor Law in an Economic Perspective

Summing the previous discussion, one may consider the *locus* of labor as a market, but in which (legal) rules are of particular importance to equilibrate powers and interests. In this manner, both economists' and sociologists'/lawyers' perspective on labor can be equally considered, in a balanced manner. The main goal of labor law in modern democracies should be to provide sound institutions that will equilibrate information, bargaining power, and contractual relationships while fostering economic growth by promoting firms' efficiency boosting. This task should involve the *creation* of rules by the executive and legislative powers and also their *enforcement* by the judiciary. Besides that, if rules to promote social indicators (such as education, health, pension, etc.) are also developed, a country should be able to truly achieve economic development.

Yet, it seems that many countries have failed in this task, either by pending too much to one side – overregulation or “bad” regulation of the labor market, hindering potential economic growth (e.g., Latin American countries, Spain, Italy,

etc.) – or by pending to the other side: lack of regulation leading to low welfare, working conditions, or inequality (e.g., Asia's developing countries and, to some degree, the USA, as compared to other industrialized countries). In some sense, this reflects a one-sided view of labor, either excessively economic or excessively based on the balance of powers.

Special Topics

In this section, we discuss the main types of regulation in some areas of labor relations. We refer to some empirical studies that try to access the impacts of these regulations in the economy.

Labor Regulation (In General)

Botero et al. (2004) analyze regulation of labor, specifically laws on employment, unionization, and collective bargaining, and social security in a sample of 85 countries. Their main result is that countries in which labor regulation is overall more invasive, have higher unemployment rates – especially of the young.

In a theoretical study, Blanchard and Giavazzi (2003) show that labor regulation creates sharp intertemporal trade-offs for workers. In the short run, workers are better off with more regulation, because their wages will be higher; yet, in the long run, regulation brings higher unemployment. In a dynamic approach – in which there are new entrant firms in the future – their model predicts that employed workers will be worse off with deregulation, both because wages will be lower and the probability of them being unemployed will be higher. On the other hand, workers who would have been unemployed without the entrance of new firms benefit either by the new possibilities of being hired or with an increase in their wages. Although this study does not include empirical observation, it seems to be a more careful analysis of the implications of regulation and deregulation in the labor market, compared to those done initially in the classical economic literature.

In the other side of the discussion – the legalistic, noneconomic literature – there have been

claims that labor regulation should be (also) approached in a transnational manner, specifically under regional integration pacts (Trubeck et al. 2000). Although the idea seems coherent, these studies would greatly benefit from a more analytical and empirical approach, which could evaluate the concrete outcomes on the overall economy, and specifically on the variables directly affecting workers and employers.

Unions

Basic economic models show that unions impact markets by raising wages of unionized workers. Consequently, employment levels decrease, since employers try to substitute those more expensive workers with nonunionized, cheaper ones. In a context where there is no perfect mobility of factors (in this case, labor is the main factor), this creates a long-lasting, perverse effect in the economy: the presence of a dual labor market (Piore 1969; Doring and Piore 1971), in which the first one is marked by the presence of unionized, high-skilled workers, earning high wages, but in which the level of employment is lower. On the other hand, low-skilled workers are trapped in the market with lower wages and, usually, worse labor conditions. This happens because due to the lack of skills, inferior workers cannot move to the first market; on the contrary, firms tend to have higher mobility and may choose to operate in either the superior or the inferior market, depending on the presence of unions and their bargaining power. If it is the case that firms are not able to choose in which market to operate, in the long run, those facing unions will lose their comparative advantage and lose business to those who do not face unions. The result will be a decline in unionization in the overall economy (Posner 2003). In countries where unionization does not happen at the firm level, the analogy holds true for different sectors of the economy: those who face unionization will lose competitiveness and may perish in the long run; the opposite is true for those sectors not facing unionization.

For some decades, empirical literature has systematically brought evidence in this direction (e.g., Borjas 2016). Yet, one study shows these effects in a careful and detailed manner and deserves a more careful attention. Aidt and

Tzannatos (2008), besides linking union activities to monetary policies in an original but important fashion, show that it is not the simple, cross-country variation in union density that affects economic outcomes (as the literature has traditionally implied). The authors bring the *coordination* and *bargaining coverages* to the spotlight. They empirically associate the existence of coordinated bargaining systems – via labor unions or other formal and informal labor organizations – to better macroeconomic outcomes (e.g., lower unemployment) and more flexible labor markets, what may sound odd at a first glimpse. On the contrary, high bargaining coverages are associated to poorer economic performance. According to these authors, bargaining coordination guarantees positive outcomes and also enables labor markets to respond more adequately and in a less adverse manner to external shocks. In an effort to employ the classical economic theory of labor, coupled with an institutional perspective, these authors conclude that “it is the total ‘package’ of (formal and informal) institutions that matters for economic performance” and that “labour market coordination cannot and should not be thought of in isolation from the broader institutional environment” (p. 290).

Minimum Wage

Economists usually regard the effects of mandated minimum wages as similar to those of unions, because unions’ most usual demand is on higher wages. As the models predict, minimum wages create unemployment, especially for marginal workers, i.e., female, young and old, and black (Posner 2003). The effect is explained by a change in relative prices between less- and high-skilled workers, the first becoming more expensive (because minimum wages are set lower than the level of high-skilled workers’ productivity, not affecting, thus, their wages). If minimum wage is applicable only to some sectors and not to others, the effect is again equal to that when there is a dual labor market, of unionized vs. nonunionized firms: it may increase unemployment in the sector covered by minimum wage and decrease unemployment in the sectors in which no mandatory wage prevails. Finally, as Posner (2003) explains, minimum

wage may hinder on-the-job training of marginal workers (those who need it the most), because employers may not compensate the costs of the training investment by paying lower wages.

This topic has brought much attention to the economic literature, and Alan Krueger calls for a “History of Economic Thought on the Minimum Wage” (2015). Traditionally, evidence brought by this literature has corroborated the classical microeconomic model, as explained above. Yet, recently some studies have questioned that explanation, by showing that the effects of minimum wages on unemployment have been overstated. Hoffman (2016), for instance, finds no impacts of increases in minimum wages on young and low-skilled workers’ unemployment. In fact, the author finds some *positive* effects of wage increases on employment for a few states in the USA. The study also presents some other recent literature corroborating its findings.

Undoubtedly, although a “history of economic thought” already exists for this theme, more empirical studies, which carefully analyze the broad implications of minimum wages on economic variables, are still needed. The story is not over.

Unemployment Compensation

Traditional economic models predict that longer and more generous unemployment compensation leads to lower rates of employment and higher wages. The explanation is that, besides having less incentives to find a job, workers are comfortable to calmly search for better jobs, i.e., their outside options increase. Yet, empirical evidence coming from the literature is not strikingly convincing in this direction. By analyzing changes in the rules of unemployment compensation in the USA during the 2008–2009 recession, Nicholson et al. (2014) find that “[unemployment coverage] extensions may indeed have had detectable effects on the U.S. labor market, but some of the studies are contradictory” (p. 212). Ludsteck and Seth (2014) for Germany in the late 1990s and beginning of 2000s, and Howell and Rehm (2009) for the OECD countries in a period of 30 years, also find contradictory empirical evidence.

This is certainly a subject which deserves more in-depth empirical and analytic studies.

Outsourcing and Subcontracting

The current phenomenon of labor outsourcing takes place under two variations: cross-border outsourcing (transnational subcontracting) and within-border outsourcing (local subcontracting). The first one is a relatively recent trend, which intensified in the last three to four decades, in which companies from industrialized countries, mainly the USA and Western Europe, move their fabric plants abroad, to countries in which labor is cheaper. They may also simply stop their own national production and purchase products from other firms and factories in those poorer locations. The second type of outsourcing happens nationally and is a much older phenomenon: a firm, with its own employees, specializes in some activity – either manufacturing, assembling, or servicing – and hires other firms and/or outside workers to do activities in which it is not specialized. For instance, an automobile firm does not produce all the automotive parts, a bank may hire another firm to provide specialized security services, a movie theater may subcontract people and firms to offer popcorns, and a school may hire a company to be responsible for the cleaning services. Subcontracting, in this sense, materializes Adam Smith’s idea of division of labor which occurs in a society.

As the technology advances, the economy gets more specialized, and outsourcing – either transnational or local – becomes more pervasive. Along with this process, trade unions and other advocates of labor’s interests (labor sociologists, labor attorneys, public prosecutors, etc.) have loudly manifested their opposition to the increasing trends in labor outsourcing. They argue that it has been responsible for the degradation of labor conditions, including the decrease in wages and the increase of unemployment: *inside* workers lose their positions, and lower-paid jobs are created for *outside* workers (located in the same country or abroad). Once again, employers and workers seem to be in opposing sides, headed to divergent directions. What does evidence show?

Actually, very controversial results. In the topic of international outsourcing, literature is almost split: those who argue that it is beneficial for workers and others showing that it is very

deleterious to workers – for those in rich and in poor countries. Bachmann and Braun (2008) show part of the controversy in the literature. However, after analyzing a big panel of data, their conclusions are positive toward outsourcing, at least for some workers in Germany. They show that German companies cross borders to hire labor in cheaper countries, workers face higher job stability, and the effect is more significant for those in the service sector and less in the manufacturing sector. Yet, the authors remark that effects are strongly heterogeneous across the skill levels and age. Specifically, international outsourcing is significantly hazardous for medium-skilled and lower workers in the German manufacturing sector.

Anner (2011) evaluates the impact of outsourcing on the other side of the story, i.e., in countries of *destination*, and finds evidence of very negative results. In Central America – specifically Nicaragua and El Salvador – outsourcing reduced workers' bargaining power (due to spatial dispersion) and led to lower wages.

With regard to domestic outsourcing, or subcontracting, Autor (2003) shows that unionized firms in the USA tend to outsource *more* than nonunionized firms. This is a counterintuitive result and offers hints that unions are not always able to guarantee rules that benefit labor. Yet, the author is cautious about welfare impacts. In Brazil, Stein et al. (2015) use official data on eight million workers and employ the methodology of “fixed effects panel data,” i.e., they compare wage effects for a particular person when he/she migrates from being an inside worker to an outsourced one and vice versa. The main goal is to control for each worker's personal (observable and nonobservable) characteristics. Their results show that, after controlling for fixed effects, wage differential between inside and outsourced workers is of 3% only. Besides that, significant wage differentials are created when outsourcing occurs for low-skilled workers under such situations, wages are 12% lower compared to inside workers with the same characteristics.

Such controversial evidence in the literature shows the need for more detailed and careful analysis on this topic.

Other Labor Issues

Posner (2003) provides brief discussions on a long list of other labor issues, such as child and female labor, health and safety at the workplace, maternity leave, employment discrimination (race, sex, age, disability), pension law, etc. However, more empirical analysis on each of these themes is still needed, and many other themes are also still left uncovered by the literature. It is also important to directly link the explanation coming from economic models to institutional evaluations: What are the effective impacts of specific labor rules? (For instance, “What are the effects of creating quotas – based on gender, race, age, etc. – at a workplace?”) What are the political, sociological, etc., concerns behind the stipulation of some labor laws? (For example, “Why should the employer be always strictly liable for damages in case of accident at the workplace? Is this the manner to minimize damage costs and probabilities of accidents? If not, what kind of rule would be more effective?”)

Our discussion above offered some initial hints. But much should be assessed empirically.

Summary

We started this entry by arguing that the literature on labor relations has been very much divided, mainly between the classical economic approach and the legal/sociological one. An economic analysis of labor law would benefit by abridging both perspectives and complementing with more. It seems that the model of labor market is a plausible one. However, it is crucial to remember that, more than other usual markets, there are strong failures in place here. There are also problems of unbalanced bargaining and political powers. Because of this, labor regulation cannot mirror simple, ordinary contract regulations. A special look is needed.

Empirical literature, unfortunately, mirror the dichotomy of the economic vs. legal approach and, for several (if not all) issues, provide contradictory, inconclusive evidence. Many times, problems might have happened due to imperfect data or inadequate methodologies. As information technology advances, as well as the quality of

databases, one might expect higher quality and, hopefully, more conclusive evidence.

No matter what, although this topic is one of the oldest themes in the social sciences, there is still room for much research.

Economic Analysis of Law

Alain Marciano

Abstract

The purpose of this entry is not to identify the central claims upon which rests an “economic analysis of law.” That goes far beyond what

could be done. Our goal is to characterize methodologically an economic analysis of law and, as a consequence, to establish and explain the distinction that exists between an “economic analysis of law” and “law and economics.”

Definition

Economic analysis of law is the field defined by the use of economics to analyze legal phenomena and the functioning of the legal system.

Introduction

The purpose of this entry is not to identify the central claims upon which rests an “economic analysis of law.” That goes far beyond what could be done. Our goal is to characterize methodologically an economic analysis of law and, as a consequence, to establish and explain the distinction that exists between an “economic analysis of law” and “law and economics.”

Usually, those terms are used interchangeably to describe any economic work dealing with law or legal rules. For instance, “The Problem of Social Cost” (Coase 1960) that represents the “origin [of ...] the modern *law and economics* movement” (Hovenkamp 1990, p. 494; emphasis added) and marks the passage from an “old” to a “new” law and economics (Posner 1975) is also viewed as the article that “established the paradigm style for the *economic analysis of law*” (Manne 1993). Symmetrically, an *Economic Analysis of Law* (Posner 1973) was viewed as “coursebook in law-and-economics” (Krier 1974, p. 1697). One could also quote Cento Veljanovski (1980, p. 160) and even Richard Posner, one of the founders of an economic analysis of law, who characterized his work as one of the “recent developments in *law and economics*” (1975, emphasis added). Many additional references could be cited that would confirm that the two expressions are usually viewed as synonymous.

Yet, sometimes, they are distinguished. In this regard, Ronald Coase is probably one of the most significant authors to quote. He explained that “two parts” coexist in law and economics (1996, p. 103; or Coase in Epstein et al. 1997, p. 1138), which are “quite separate although there is a considerable overlap” (Coase 1996, p. 103). The first part corresponds to what is called law and economics and implicitly corresponds to the analyses to which Coase attached his name. The second part, to which “Judge Posner is the person who has made the greatest contribution” (Coase in Epstein et al. 1997, p. 1138), is “often called the economic analysis of law” (Coase 1996, p. 103).

This is the distinction we want to emphasize in this text. Our point is that a better understanding of an “economic analysis of law” requires careful understanding of the differences with “law and economics” and, therefore, a careful understanding of what is law and economics.

A Negative Characterization of an Economic Analysis of Law: Law and Economics

In a “law and economics” approach, the focus is put on the economy, the economic system, or economic activities, and, since economic activities take place in an institutional, legal environment, a correct understanding of the economy and of economic problems requires to take into account how and how far legal rules do affect the economy. This is precisely what law and economics is. This is exactly what Coase did in “The Problem of Social Cost (1960).” He “used the concept of transaction costs to demonstrate the way in which the legal system could affect the working of the economic system” (Coase 1988, p. 35). Later, he added: “[F]or me, ‘The Problem of Social Cost’ was an essay in economics. It was aimed at economists. What I wanted to do was to improve our analysis of the working of the economic system” (1993, p. 250). From this perspective, Coase was one of the founders of “law and economics” in its modern form but not of an economic analysis of law.

What is important to correctly understand the distinction between law and economics and economic analysis of law is that a law and economics approach rests on a definition of economics by scope, object, domain, or subject matter. In other words, what distinguishes economics from other social sciences is that each of these sciences has its own subject matter. Once again, this was the perspective explicitly adopted by Coase, for whom “economists do have a subject matter” (1998, p. 93). It corresponds to “certain kinds of activities” (1978, p. 206) or, more broadly, “the working of the economic system, a system in which we earn and spend our incomes” (1998, p. 93). Or, in a slightly different way, economists study “the working of the social institutions which bind together the economic system: firms, markets for goods and services, labour markets, capital markets, the banking system, international trade, and so on” (1978, pp. 206–207). In other words, economists study the activities that take place on explicit markets. That’s the only set of activities that they can analyze with their tools. Coase again: economists “should use these analytical tools to study the economic system” (1998, p. 73).

This view has two implications. The first one is that economists should not study what is outside of the scope of their discipline, in particular legal rules, legal phenomena, and legal cases. They do not fall into the subject matter of economics and are not studied by law and economics. They are important but *only* to give “details of actual business practices (information largely absent in the economics literature)” (Coase 1996, p. 104). Second, law and economics does not only exclude certain objects from its domain of investigation and also excludes noneconomists from the analysis of economic activities. Coase was very clear about that: the subject matter is “the dominant factor producing the cohesive force that makes a group of scholars a recognizable profession” (p. 204), “the normal binding force of a scholarly profession” (p. 206), and what “distinguishes the economics profession” (p. 207). Thus, the delimitation or delimitation of the scope of economics establishes a distinction with other social sciences and guarantees the unity and the autonomy of economics.

What Is an Economic Analysis of Law

By contrast with “law and economics” presented above, an economic analysis of law implies a radical change in the object of study. The focus is no longer put on economic activities – defined as the activities that take place on markets – and the objective is no longer to understand how legal rules influence the economy. The legal system is no longer seen as the environment in which economic activities take place and therefore external to the object of study – the working of the economic system. It becomes the object of study. In fact, and very straightforwardly, an economic analysis of law consists in using economics to analyze the legal system and how it works or, to quote Lewis Kornhauser, “Economic analysis of law applies the tools of micro-economic theory to the analysis of legal rules and institutions” (2011). This means, in particular, that legal rules are no longer taken as given and exogenous. An economic analysis of law endogenizes legal rules. To quote Posner, an economic analysis of law consists in “the application of the theories and empirical methods of economics to the central institutions of the legal system” (1975, p. 39).

From a methodological perspective, an economic analysis of law rests on and requires a specific definition of economics – completely different to the definition of economics used in law and economics; the difference in definition of economics is such that it makes law and economics and an economic analysis of law incompatible. Indeed, an economic analysis of law does not and cannot rest on a definition of economics by subject matter or by scope or by domain, as it is the case with law and economics. Analyzing the working of the legal system is possible and legitimate, only if the very idea that there exists a subject matter specific to economics, to which economists should restrict their attention, is abandoned. Otherwise, there would be no justification to analyze, among other things, the behavior of criminals, judges, prosecutors, or attorneys and any of the phenomena that are usually studied in economic analyses of law. These behaviors and phenomena are not,

strictly speaking, of economic nature because they do not take place on markets. They can be studied by economists only because it is assumed that any kind of activity and of behavior or any phenomenon, even those taking place outside of markets, can be studied by economic theory. This is exactly the view adopted and promoted by Gary Becker who stressed that economic theory “applies to both market and nonmarket decisions” (1971, p. viii) or “the economic approach is clearly not restricted to material goods and wants, nor even to the market sector” (1976, p. 6).

Let us note here that such a change in perspective – the expansion of the domain of economics beyond its “traditional” boundaries – is a consequence of the assumption that no difference exists between market and nonmarket behaviors. Individuals are supposed to *always* behave in the same way. As Becker wrote, “human behavior is not compartmentalized, sometimes based on maximizing, sometimes not, sometimes motivated by stable preferences, sometimes by volatile ones, sometimes resulting in an optimal accumulation of information, sometimes not” (1976, p. 14).

This then means that all social sciences have exactly the same subject matter. All social sciences can study the same behaviors and the same phenomena. The only difference that exists between them is the method or the approach they use (Becker 1971). Then, from such a perspective, economics is defined or rather described or characterized – Posner (1987, p. 1) argued that economics cannot be defined – by its method. Economics is a “way of looking at human behavior” (Becker 1993, italics added). To use Posner’s words, economics is “a powerful tool” (1973, p. 3) or “an open-ended set of concepts” (Posner 1987, p. 2), which can be used to analyze any kind of human or social phenomenon – including legal ones. Then, “when used in sufficient density these concepts make a work of scholarship ‘economic’ regardless of its subject matter or its author’s degree” (Posner 1975). It is only if this definition of economics is adopted that an economic analysis of law is possible.

A Few Historical Landmarks

Cesare Beccaria and Jeremy Bentham – sometimes Gladstone (see Posner 1976) – are viewed as the “predecessors” (Stigler 1984, p. 303) of an economic analysis of nonmarket behavior (among others: Posner 1975, 1993, p. 213) and, more specifically, of economic analyses of crime and punishment. Indeed, they were the firsts to analyze illegal behaviors and illegitimate activities as the result of an “economic calculus” (Becker 1968, p. 209) or of a “rational choice” (Posner 1993, p. 213).

In the twentieth century, the first who developed an economic analysis of law is Guido Calabresi in the early 1960s. In “Some Thoughts on Risk Distribution and the Law of Torts (1961; see also Calabresi 1965)” by contrast with Coase, Calabresi used economics to analyze a legal problem – namely, the compensation of victims of car accidents in different systems of liability. This was acknowledged by Walter Blum and Harry Kalven (1967, p. 240), Posner (1970, p. 638) and Frank Michelman (1971, p. 648). However, Calabresi also insisted that his work should not be viewed as a form of economic analysis of law. We suggested elsewhere that his analysis should be viewed as a form of heterodox economic analysis of law, mainly for two reasons. First, he rejected the behavioral assumption that economic analyses of law use – individual rationality. Second, he eventually criticized standard – read, Posnerian – economic analyses of law because it assumes that the “world” – the conditions in which individuals act and live – is given and by analyzing how individuals chose in a set of given conditions. To him, the law could be used to change the world and not to promote its economic efficiency (Kalman 2014). In other words, Calabresi claimed that economics, and economic analyses of law, should not be only about the allocation of resources. And, one could add, Calabresi did not make the methodological move of explicitly defining economics as a method.

It was Becker who did this move, because and when he was the first economist who consistently and repeatedly used economics to analyze

nonmarket behaviors and to explicitly define economics as an “approach.” Among his writings, “Crime and Punishment: An Economic Approach” (1968) must be singled out as the first (modern) economic analysis of a legal problem, namely, crime and illegal behaviors. Indeed, Becker was the first to explain crime as the result of a rational decision, of an economic calculus, that is, of the comparison of costs and benefits. As mentioned above, this comes from the idea that all human behaviors are of the same nature and can be explained as if they were rational, an assumption that remains crucial to an economic analysis of law.

However, Becker’s direct contributions to an economic analysis of law were scarce. The ones who really founded an economic analysis of law are William Landes, Isaac Ehrlich, and Richard Posner.

Landes and Ehrlich were Becker’s PhD students (Fleury 2015, 2016). They transformed Becker’s insights into a specific field of research. Ehrlich studied the participation in illegitimate activities and deterrence (1967, 1970), and Landes analyzed the effects of fair employment legislation on the well-being of discriminated nonwhites (see Fleury 2014). Also of particular importance, Landes was the first who developed an economic analysis of courts (1971). Landes’s work was important because it was the first to really propose a model of the working of the judicial system, taking into account the two sides of the legal “market.” Thus, while Becker had introduced the assumption that criminals are rational, Landes introduced the assumption that prosecutors also are rational.

Landes played also an important role for having involved Posner in a program in law and economics launched by the National Bureau of Economic Research (Landes 1998). Posner became one of the most important figures in economic analyses of the law. Not only he invented the expression, in the title of his 1973 book, and launched the first journal devoted to an economic analysis of law – namely, the *Journal of Legal Studies* – but he also contributed to explicitly define the field, providing its methodological bases and incessantly opening up new domains

of analysis. He is one of the most important – quantitatively and qualitatively – contributors to the field. Posner’s contribution cannot be described or summarized, and, accordingly, it could be said that it is particularly difficult to summarize an “economic analysis of law.” However, let us note that Posner generalized the use of the assumption that individuals are rational in economic analyses of law; in particular, he developed and expanded the analyses of judicial decision making – explaining that judges make their decisions by maximizing a utility function. Actually, Posner linked this claim to another claim about the efficiency of the law, at the same time a positive and normative claim. Rationality and efficiency are two central claims, maybe the two pillars upon which rest economic analyses of law.

Conclusion

We suggest to distinguish between “law and economics” and an “economic analysis of law.” An economic analysis of law is based on a definition of economics as a method, a (set of) tool(s) that can be used to analyze the functioning of the legal system. The distinction was invented in the early 1970s but remains central to understand most of the analyses made at the intersection of economics and the law.

Abstract

Economic development describes a process of improving economic and social well-being of people in a specific area. In addition to qualitative and quantitative growth, it includes social and environmental aspects. For this purpose various economic measures with different focus are used to quantify economic development.

Introduction

The term economic development is generally used, but there is no clear definition of it. In

general the economic conditions and the standard of living are associated with it. Especially economists tend to consider economic development in terms of economic growth. Economic growth is the percentage change in the amount of a value from one period to another. In general there is a close relation between economic development and the growth of output in an economy. Economic growth describes just a quantitative change in the level of an economic measure. Beyond this development, it describes the improvement of economic and social conditions as a whole including qualitative as well as quantitative measures. Economic growth and economic development are different categories, but for explaining the economic development is a definition of the economic growth useful.

From the Economic Growth to Economic Development

A commonly used instrument to measure economic growth is the “gross domestic product” (GDP). There are three different approaches to measure it. Considering the GDP in terms of expenditures, it is defined as “the sum of the final uses of goods and services (all uses except intermediate consumption) measured in purchasers’ prices, less the value of imports of goods and services” (OECD a). The other approaches regard it in terms of income and production. Thus, it summarizes the economic power within one country into a number. Furthermore, it contains economic acting of all people within the borders of the country without taking in consideration of nationality. From this, economic growth describes the percentage change in GDP from one period to another. In general, values are reported quarterly, as well as yearly. The “gross national income” (GNI) is quite similar to the GDP, but it considers all citizens of a nation, even if they work in another country.

To refine the GDP, a per capita adjustment is used. It is calculated as the quotient of GDP and the number of residents. However, it is independent of any distributional dimension. Therefore, the GDP per capita does not refer to real

distribution, it is just statistical. In relation to population, one can distinguish between extensive and intensive growth. Extensive growth describes an increase in GDP without an increase in its per capita. Contrary to this, intensive growth describes itself as an increase in the level and per capita. To compare the GDP above countries, different price levels are taken into account with purchasing power parities. This adjustment uses baskets of goods to compare the purchasing power between countries.

Despite the advantages of the GDP, it is criticized frequently for excluding social and environmental issues. It should be noted that natural disasters can have positive impacts on it. Additionally, labor without payments as voluntary work or work at home is not included in the computation. Especially illegal work takes place as an estimation. Detailed information about the critics on GDP and the difficulties of measuring development are provided by Stiglitz et al. (2009).

It is usual to describe the economic growth by the model of economic growth. One approach to model growth was made by Harrod and Domar. They were influenced by “Keynesian” economic theory and developed models based on a connection between capital stock and production volume (Domar 1946), as well as investments and aggregate demand (Harrod 1939). The “neoclassical” approach of modeling growth goes back to Solow (1956). He developed a model laying down a long run equilibrium between investments and depreciation. As soon as the optimal capital stock is reached, the per capita income will not increase any further. Additional growth can only be achieved by technological progress. With respect to the utility maximization of the households, the “Ramsey-Cass-Koopmans Model” was modeled by Ramsey (1928) and expanded by Cass (1965) and Koopmans (1965). Different to the “Solow Model,” it considers the saving rate as endogenous depending on the optimization of infinitely living households. However, the technical progress is taken into account as exogenous. This critic encouraged Romer (1990) to develop a new model with endogenous technological change, depending on preferences of the households. However, the “Ramsey-Cass-Koopmans

Model” is the approach most commonly used in growth theory.

Measures of Economic Development

To describe and measure the economic development of economies on an easy way, the World Bank offers a classification by income every year. The current values (2014) state that a GNI per capita of \$1,045 per day or less describes a low-income economy, and the range from \$1,045 to \$12,746 describes middle-income economies. Countries with a GNI per capita and day over \$12,746 are referred as high-income economies. Besides that, low- and middle-income economies are denoted as developing economies (The World Bank 2015). Another classification is used by the United Nations (UN). To define less developed countries, three conditions are used: low per capita income, human assets, and economic vulnerability (UNCTAD 2015).

Taking into consideration those critiques on the GDP and the insufficiency of quantitative indicators to measure development, it is comprehensible that many alternative measures have been developed. The UN supports the “Human Development Index” (HDI), which includes live expectancy at birth, education, and the “gross national income” per capita to measure the development more adequately. Live expectancy at birth and education are used as more qualitative indicators, even if they are numerical measures. Education is taken into account with years of schooling from educated people and the expected years of schooling of uneducated people. Live expectancy is determined by average life span at birth.

Developed countries are reported at a HDI value over 0.8. Less developed countries are reported with a HDI in a range from 0.5 to 0.8, while some sub-Sahara states reported with a value under 0.5. Besides that, the HDI is highly correlated with the GDP, which is why it is criticized as being an inadequate measure of economic development too.

Regarding the distribution of wealth, the “Gini coefficient” is commonly used. It states a value

between zero and one (other scaling is possible), depending on the division of income, whereby a value of zero declares the complete equality in income and a value of one states the contrary. From that it is used as a measure of equality in a society. The OECD countries are reported with a value of 0.32 in 2012 (OECD b).

One famous critic on economic growth came from Meadows et al. (1972). This survey simulated growth scenarios considering world population, raw materials, and environmental pollution. In this context the term “qualitative growth” took place in the discussion. In contrast to “quantitative growth,” it considers issues as health, education, security, and equal opportunities in addition to the GDP.

As an alternative to the GDP, Bhutan proposed the “gross national happiness” (GNH) to measure economic development. It considers social justice, environmental protection, good governance, as well as cultural values. However, it is difficult to measure those qualitative indicators and make them comparable. As the consequence, the GNH was not successful.

Moreover, critics on the GDP took place in the discussion, so the German “Federal Office of Environment” proposed the “national wealth index” (Diefenbacher et al. 2010). It includes many indicators related to environmental issues, mobility, security, health, income, and consumption.

Independent from these approaches, many measures of economic development are existing, not just considering the growth.

Economic Efficiency

Ram Singh
Department of Economics, Delhi School of
Economics, University of Delhi, Delhi, India

Definition

The term Economic Efficiency refers to the relationship between aggregate benefits and costs to the individuals concerned. Among the widely used efficiency criteria are the Pareto Optimality, the Kaldor-Hicks, the Cost-Benefit, and the Wealth Maximization criterion (Hicks 1939; Jain 2015; Jain and Singh 2002; Kaldor 1939; Sen 1970 and Scitovsky 1941). In this essay, we discuss economic efficiency as a tool for the social choice among the alternative legal rules. Discussion is carried out by using illustrative examples. We show that in several contexts the efficiency

can serve as a useful tool for comparing the legal rules. However, it has serious limitations as well. In several situations, the efficiency criteria can fail to compare legal rules or can lead to contradictory rankings. Moreover, the assumptions underlying some of the efficiency criteria do not hold always. We discuss merits and demerits of various efficiency criteria. It is shown that in the real world, economic efficiency has limitations as a guide for making social choice from among the legal institutions.

Introduction

The aim of the economic efficiency is to maximize the aggregate net benefits for the individuals concerned. It serves a useful tool when the objective is to maximize the net economic gains for the individuals involved. A strand of law and economics literature uses economic efficiency as a yardstick to compare outcomes under different legal rules or institutions. In other words, economic efficiency is used as a basis to compare and rank the legal rules and institutions.

The law and economics researchers use several efficiency criteria. Notable among the frequently used ones are the Pareto optimality, the Kaldor-Hicks, and the Wealth maximization criterion. In several legal contexts, these criteria can serve as a useful tool for comparing relative efficiency of the legal rules. However, on several occasions, these criteria can fail to compare various alternative legal arrangements.

For the ease of illustration, let us start with an example. Suppose there are 50 fishery units located on a water stream. Each unit earns a profit of 15 for its owner. There is plan for a cloth factory to start at upstream. If factory starts, it will generate a net profit of 600 for its owner. However, the factory will discharge chemicals in the water stream. The polluted water is going to be injurious to the fish. In the absence of any corrective measure, assume that the fisheries will suffer a harm of 10 each, that is, a total harm of 500. To keep things simple, we can assume that the factory has no other effects, good or bad, on the fisheries and also for any other third party. Moreover, assume if

a chemical treatment device is installed at the factory, it can completely solve the problem of water pollution. The device will cost 501. Now consider the following legal arrangements.

Rule 1: The factory is allowed to operate but will have to fully compensate the fishery for the loss inflicted on them – “full” compensation means that the profit of fisheries will be restored 15 each, i.e., the profit levels in the absence of the water pollution caused by the factory (see Singh 2004, 2007a). *Rule 2:* The law does not allow the factory to operate at all. Clearly, under this rule profitability of fisheries will remain unaffected. *Rule 3:* The factory is allowed to operate without any obligations to compensate the loss suffered by the fisheries. In this case, the profit enjoyed by the fishery owners will come down from 15 to 5. *Rule 4:* The factory is allowed to operate only with the treatment device installed, and half of the cost of the device is to be borne by the factory owner and the remaining half is to be split equally among the fishery owners.

Suppose the factory operates without the treatment device. Then, even after fully compensating the fisheries by paying them 10 each, the factory owner will be left with a profit of 100. Therefore, Rule 1 is more desirable than Rule 2. A shift from Rule 2 to Rule 1 makes one party better off (owner of the factory) without reducing well being of anyone else. This argument in favor of Rule 1 over 2 is at the heart of the widely used efficiency criterion called “Pareto optimality.”

Pareto Optimality

According to the Pareto optimality criterion, a rule or state of affairs x is Pareto superior to another state y if and only if the following conditions are satisfied: (a) every concerned individual or party involved considers the state x to be at least as good as the state y ; and (b) at least one person strictly prefers x over y . Under such a scenario, every individual will either strictly prefer x over y or will be indifferent between the two options. In our example, clearly Rule 1 is Pareto superior to Rule 2. In fact, if the factory owners were to pay 11 to

each fishery owner, all parties can be made better off compared to their well being under Rule 2.

The argument can easily be extended to the social desirability of legal arrangements. A legal rule x is Pareto superior to rule y if at least one person strictly prefers x over y and everyone else is indifferent between the two. Extending the argument further, alternative x is called Pareto optimum if there is no other legal arrangement which is feasible and is Pareto superior to x . In other words if x is Pareto optimal, then there cannot be an alternative t which is available as a social choice option and is Pareto superior to x .

This point can be seen by relabeling Rules 1 in the above example as alternatives x and Rule 2 as y . Further, label Rule 3 as z and Rule 4 as w . So the set of legal alternatives which are available for social choice can be written as

$$L = \{x, y, z, w\}$$

Now, it is easy to see that legal rule x is Pareto superior to rule y . In a meaningful sense, rule x is socially more desirable than y . Therefore, the value judgment based Pareto criterion is rather appealing. If a feasible state of society say u is Pareto superior to some other state v , then plausibly u is socially more desirable than v .

From the definition, it is clear that Pareto optimality of a rule or an alternative is defined with respect to the given set of alternatives and the set of individual concerned. Any change in either of these sets can alter the optimality status of a rule or a social choice option. For instance, in our factory-fisheries example suppose for some reasons the alternative x is not available anymore. Then the social choice set will be

$$L' = \{y, z, w\}$$

where y , z , and w are the legal alternatives as defined above. Now, y becomes Pareto optimum since neither z nor w is Pareto superior to y .

Moreover, Pareto criterion can easily fail to compare the alternatives available and thereby fail to be a guide to the social choice process. To see this, consider a comparison among Rules 2 and 3, i.e., legal arrangements y and z . It can

be seen that neither y is Pareto superior to z nor the other way round. Similarly, it can be seen that legal rule x and z are not comparable on Pareto criterion. In fact, in any choice situation involving alternatives u and v if one party strictly prefers u over v and another strictly prefers v over u then the two alternatives cannot be compared, regardless of how the rest of individuals in the society feel about these two alternatives. Moreover, if the choice involves only two such alternatives, then both will be Pareto efficient!

This shows a serious shortcoming of the Pareto criterion. In real world, the social choice involves legal changes which lead to net gains to some citizens but impose net cost on the others. Specifically, consider a change in the legal status-quo such that the proposed change entails net gains to most citizens but imposes net cost on a few members of the society. Under such situations, the Pareto criterion cannot be the guide to decide between the proposed change versus the status-quo.

Kaldor Efficiency

What is known as the Kaldor efficiency criterion aims to overcome the above limitations of the Pareto criterion. According the Kaldor criterion, a shift from alternative y to x is better if the gainers can compensate the losers and still be better-off. It is noteworthy that according to this criterion, the gainers are not required to actually compensate the losers – only requirement is that in principle they should be able to do so. On this logic, if we revisit the comparison among the Rules 2 and 3, Rule 3 is better than Rule 2 – since the gainer (factory owner) benefits by 600 out of which he can fully compensate fisheries by paying 500 and still be left with a net gain of 100. It can easily be seen that in the above example, each one of the Rules 1, 3, and 4 is better than Rule 2. In other words, alternatives x , z , and w are Kaldor superior to y . Legal alternatives x and z are equally efficient, and both are better than the 4th rule, i.e., the alternative w . The point is that unlike the Pareto criterion, the Kaldor criterion can compare all of the above legal alternatives. In general, the social

ranking can be produced by a pair wise of comparison of the alternatives.

The Kaldor criterion is the basis of the widely used cost-benefit and wealth maximization efficiency criteria. Going back to our earlier example, a shift from rule y to rule x imposes a cost of 500 on fisheries but entails a benefit of 600 to the factory owner. Since the benefit is greater than the resultant costs, the cost benefit criterion will rank x better than y . By similar logic, rules x , z , and w are superior to y .

Wealth Maximization

The wealth maximization criterion ranks the alternatives according to the levels of total wealth under them. On this count too, compared to legal rule y , under each one of the rules x and z the total wealth for all the parties involved is higher by 100; under w the corresponding figure is 99. Therefore, these rules are superior to the rule y according to the wealth maximization criterion. The rules x and z are all equally good. Moreover, these two alternatives are socially best, since under these rules the level of wealth is maximized.

It can be seen from the above discussion that the Kaldor, the cost-benefit, and the wealth maximization criteria provide a similar ranking of the legal rules. Moreover, the social ranking produced is complete, in that using these criteria we can compare any two legal rules. However, it should be noted that the virtues of these three efficiency criteria hold under the assumption that the wealth level is the sole determinant of individual utility levels (well beings). In the above discussion, our underlying assumption has been that well being of each party involved increases with the monetary gains enjoyed by the party.

The Kaldor criterion also serves as a useful metric when production and consumption choices involve only one good and the individual utility functions are increasing in the amount of good consumed. In that case, the criterion requires allocation resources to maximize production of the good. Once that is done, any distribution of the good among consumers is Kaldor efficient. However, such assumptions are restrictive.

Limitations of Efficiency Criteria

In real world, the consumption basket has numerous goods and services in it. Besides, the utility levels may depend on factors other than the individual consumption levels of goods and services. In several such contexts, the Kaldor criteria and its derivatives can lead to contradictory or inconclusive ranking of legal choices. Moreover, several decision makers may be guided by the non-economic considerations or might not be able to work in line with the objective of economic efficiency (see Singh 2003 and Schäfer and Singh 2018). Therefore, the real world applicability of the efficiency criteria is limited.

On top of it, the efficiency criteria completely ignore the issue of fairness, equity, and justice which can be paramount considerations when it comes to choosing from different legal regimes. Nonetheless, these criteria are widely used in law and economics. On account of the ease of working with it, most of the economic analysis of legal rules and institutions is based on the wealth maximization criterion. For a discussion on the underlying assumptions, the use, and the debates surrounding the use of this criterion see, R. A. Posner (1985). For use of the criterion in specific contexts see Singh (2007a, b) and Schäfer and Singh (2017).

Economic Growth

Maria Rosaria Alfano

Economics Department, Seconda Università degli Studi di Napoli, Italy

Abstract

Considering its quantitative property, economic growth has often been considered an index of wealth. Nonetheless, it does not represent the well-being of a given country. In fact, it lacks information on how this wealth is redistributed or on the indirect effects of the said production, such as environmental consequences. Economic literature highlights the difference between economic growth and development, attributing to the latter a holistic definition, which takes into account additional factors, such as collective well-being, social equity, life expectancy, quality of institutions, and environmental quality. Although, at a first glance, the boundaries between concepts of growth and development may be considered as clearly distinguishable, they often tend to disappear when analyzing the two variables

from a long-term perspective. In both economic theory and practice, there are several significant variables, such as the quality of human capital and institutions or environmental efficiency, which play a key role in the opportunities for development in most high-income countries. Within this framework, development becomes a fundamental feature of economic growth, when the latter is interpreted as a general improvement in quality of life, as opposed to a mere quantitative increment in production.

Definition

Economic growth is the increased capacity of an economy to produce goods and services, comparing one period of time to another. It is measured through the growth rate of the gross domestic product (or gross national product, or national income), which is calculated in real terms in order to obtain an indicator that is not influenced by inflation.

Economic Growth

Three main approaches are attributed to economic growth theory:

- Classical economists – with authors such as Smith (1776), Malthus (1798), Ricardo (1817), Ramsey (1928), Young (1928), Schumpeter (1934), and Knight (1944).
- Keynesian and neoclassical economists – who can be divided into two categories, characterized by the different role that technology plays in the production function. On the one hand, Solow (1956) and Swan (1956), Cass (1965), Koopmans (1965) regarded technology as a given variable and built models of what is referred to as exogenous growth. On the other hand, Keynesian authors, such as Harrod (1939) and Domar (1946), as well as some neoclassical authors, such as Romer (1986), Lucas (1988), Rebelo (1991), Grossman and Helpman (1991), and Aghion and Howitt

(1992, 1998), directly included technology variables into the production function, implementing models of what is referred to as endogenous growth.

- Modern economists – who are all the economists interested in the immaterial aspect of growth and in the role of institutions in the economy. The most important authors in this category are North (1990), Evans (1995), Coleman (1990), Putnam (1993), Fukuyama (1995), and Sen (1999).

A different classification of economic growth theories is based on the perspective of divergence or convergence of the economies of different nations (de la Fuente 2000). Conventionally, convergence is considered when poorer economies grow at higher rates than richer ones, thus reducing income differences between them. Subsequently, divergence is determined by the opposite mechanism. According to the former, a general equalization of income levels would be observed in the long run, while an increase in the existing gap is expected when considering the latter. Indubitably, the source of such discrepancies lies in the differences in the formulation of the production function and of technological progress dynamics. Specifically, one of the conditions for economic convergence is the presence of decreasing returns to scale, which allows poorer economies, with initially lower levels of capital, to grow faster than the richer ones. Similarly, increasing returns to scale bring about divergence between the economies of different nations. Another element that characterizes the long-run growth path is related to technological progress. Though widely accepted that an increase in technological investment ensures higher future growth rates, it is not clear whether this would ultimately lead to a convergence or divergence effect. In fact, since significant differences in growth rates are not sustainable, if the technological return is a decreasing function of its accumulation, equalization in the level of technical efficiency will be observed. Finally, another factor of convergence is associated to the allocation mechanism that allows focusing investment where productivity and return on capital are greatest. Since investment

in poorer countries is concentrated in the agricultural sector, which is characterized by low labor productivity, the reallocation of resources towards the manufacturing sector allows for a rapid increase in mean productivity. Such a boost is not feasible in rich countries, where investment is already focused in highly productive sectors.

Classical Economists

When individually analyzing the three theoretical approaches to economic growth, one can immediately recognize that, aside from the main basic concepts, the classical literature contains some crucial perspectives that would later be reconsidered in modern theory. In his book *An Inquiry into the Nature and Causes of the Wealth of Nations*, Smith, founder of modern economic science, considers a nation's growth as the result of an enhancement in productive processes, which delivers an increase in wealth and production with the same resources. The latter is made possible by the augmentation of labor specialization, given by an increase in production and knowledge. Thus, the issue of low resources is overcome through enhanced efficiency. Continuous growth in the economy is thereby guaranteed.

Ricardo, on the other hand, expresses a different view on the matter, focusing on the problem of income distribution and its impact on economic development. Motivated by the conviction that development depends on the accumulation of capital, in other words, the share of profits devoted to investment, Ricardo dedicated his work to the study of the determinants of capital accumulation. With reference to an economy composed of landowners, capitalists, and workers, though no technical progress, the author showed how an increase in production could only be achieved through a greater exploitation of the employed labor force and cultivated land. According to his analysis, this process leads to a rise in rents and a continuous reduction in profits (due to the diminishing returns on land), thus discouraging investment and hampering growth. The economist Thomas Malthus, who studied the problem of long-term growth from a demographic perspective, also reached a similar conclusion. In this case, one of the key hypotheses is the absence of

technological progress. The main assumption behind Malthus' work is the existence of a positive relationship between the wealth of a nation and its birth rate. Specifically, he argued that any wage level in excess of the subsistence one would incentivize individuals to expand their families, thus resulting in an increased consumption of resources for the livelihood of the population and a reduction in the proportion devoted to the accumulation of capital. Therefore, for Malthus as for Ricardo, the long run is inevitably characterized by stagnation of the economy, unless (as in China) policies directed towards controlling the level of births are implemented.

Technology is once again the fulcrum and engine of economic growth in Schumpeter's theory. The latter emphasized the entrepreneur as being the heart of the innovation process that allows the generation of short-term monopoly profits. The guarantee of compliance to rights (patents) protects the investment made by firms in the field of research. Like Smith, Schumpeter also argued that the accumulation of knowledge and the implementation of human capital produce increasing returns in the long run.

Nonetheless, this model is differentiated by the fact that entrepreneurs see innovation as the primary goal of their activity, because competition between firms is entirely based on the destruction of the monopolistic position of competitors and the acquisition of a market niche. This process, defined as "creative destruction," brings the economy into a market characterized by monopolistic competition, where increasing returns are the consequence of continuous increments in production technology and human capital. The State's role in facilitating the process of economic growth becomes crucial therefore it is based on the implementation of policies capable of creating the most fertile conditions to allow businesses to grow and create knowledge and innovation in a specific area. The said policies are economically justified when considering how avoiding less than optimal production becomes the goal of public intervention. The explicit introduction of technology in the production function also allows for the comparison of this model to those of endogenous growth.

Keynesian and Neoclassical

The Great Depression gave rise to a new generation of economists, who set out to reinterpret and reconsider the main features and determinants of economic growth, through the application of new formulations of the production function. Working within a Keynesian framework, Harrod (1939, 1942), and Domar (1946) were the first to highlight the instability of the capitalist system, given by the low substitutability between factors of production. Nonetheless, this hypothesis was overcome by Solow (1956, 1957) and Swan, who used a different production function to develop a model that had diametrically opposite consequences on economic growth. According to the latter, in the absence of technological improvements, per capita growth would tend towards a steady state (Uzawa 1965). The consequent assumption of the said model is that of convergence among different countries (Barro and Sala i Martin 1992, 1997). Subsequently, Romer (1994) and Lucas (1988) developed an analysis that took into account reproducible factors within the production function. The assumption of diminishing returns to capital was thereby overcome and endogenous growth models started to be developed.

In order to better grasp the theoretical journey described above, let us consider a generic production function with two factors of production, capital and labor: $Y_t = F[K_t, L_t, t]$, where Y_t is the production level at time t . In this expression, time takes on a role of proxy for technological development, given that, assuming equality of capital and labor, there will be a higher production level at time $t + 1$ compared to time t . The increase in capital stock at any given moment will thus be given by $\partial K / \partial t = I - \delta K = s F(K, L, t) - \delta K$, where δ is the depreciation of capital and I the level of investment, expressed in the latter part of the equation as the savings rate ($0 < s < 1$) multiplied by the abovementioned production function.

Harrod and Domar's model presents a peculiar formulation of the production function. The latter is that put forward by Leontief (1941); in other words it consists in fixed coefficients that could be

expressed as $Y = F(K, L) = \min(AK, BL)$, with A and B being positive constants. The equilibrium condition given by the full employment of factors of production is achieved at the point where $AK = BL$, whereas when the quantities of labor and capital invested are not at equilibrium, there will be cases where $AK > BL$ or $AK < BL$. In the first case scenario, only an amount of capital $(B/A)L$ would be exploited; just as in the second case scenario, it would only be an amount of labor $(A/B)K$. These two situations would imply, respectively, an underuse of capital and labor. The hypothesis of non-substitutability implied in this production function translates into a process of continued instability, as a result of the typically Keynesian animal spirit reasoning. Thus, when starting from an ideal condition of general equilibrium, where the economy's growth rate (g) is equal to the growth rate in production (g^*), there would be a surplus of supply together with a recessive spiral any time that $g < g^*$ and, vice versa, an excess in demand with inflationary expansion whenever $g > g^*$. This process would inevitably result in an economic growth determined by macroeconomic unbalance and lacking any sort of natural force that could allow for long-term equilibrium.

With the aim of overcoming the limitation posed by the non-substitutability of factors of production, the Solow-Swan model utilizes a typically neoclassical production function. This model is characterized, first of all, by the absence of a technological development variable and thus of the properties typically attributed to functions that do include the latter: namely, the factors of production have a decreasing marginal productivity, the function presents constant returns to scale, and the marginal product of capital (or labor) is infinite for K (or L) tending to zero and zero in the opposite case scenario. Through the application of this specific production function, it is possible to reformulate the equation that explains the variation of capital stock over time as $\partial k / \partial t = s f(k) - (n + \delta) k$, where all variables are expressed in per capita terms and (n) represents the population's growth rate. This equation highlights that the capital's possible evolutionary routes would be:

- $s \cdot f(k) > (n + \delta) \cdot k$: arginal increase in capital over time
- $s \cdot f(k) < (n + \delta) \cdot k$: marginal decrease in capital over time
- $s \cdot f(k) = (n + \delta) \cdot k$: constant growth in capital, in other words, characterized by the per capita values (k , y , c), which remain constant over time, and the levels of these same variables (K , Y , C), which grow at the same rate as the population (n)

In Solow and Swan's envisioning, the first two cases are unstable and converge towards the third, which represents the only long-term equilibrium possible. This is instantaneously apprehended if $s \cdot f(k)$ is interpreted as the savings quota destined to investment and $(n + \delta) \cdot k$ as the real depreciation of capital. Net investment will always be positive in the first case and negative in the second, whereas there will be no incentives to changing the level of capital in the third case scenario. Convergence towards the steady state is inevitable, determining in the long term an absolute condition of equality between countries de la Fuente (2000). According to the authors, the countries starting with similar conditions will immediately converge to the same steady state, while the ones starting off as more disadvantaged will grow at a faster rate, to then also converge. This framework, known as absolute convergence, has been criticized by Barro and Sala i Martin (1992, 1997, 2004), who sustained conditional convergence. The latter differs from the former in that it takes into account structural differences between countries.

The decreasing marginal productivity of factors of production plays a fundamental role in ensuring the process of convergence (Baumol 1986). During the 1980s, the growing international integration, together with the need to take into consideration variables that could capsize this hypothesis, led many economists to study and develop new models that could identify growth paths from within the production function. A simplified formulation of the said models is given by the equation $Y = AK$, where A represents a positive constant for the level of technology. In comparison to the production

function developed by Solow-Swan, this one is characterized by the absence of decreasing returns given by the presence of non-reproducible factors in K , particularly human capital. The latter's increasing returns counterbalanced the decreasing returns to capital, resulting in complex constant returns for each individual enterprise. When considering these new assumptions, convergence is no longer guaranteed, be it absolute or conditional. Other approaches aimed at eliminating decreasing returns to capital are based on the concept of learning by doing, introduced by Arrow (1962). The latter consists in the possibility of implementing productivity simply according to the experience acquired during previous production cycles (Sheshinski 1967). Starting from this intuition, first Romer and then Lucas implemented growth models where the accumulation of physical and human capital still guarantees constant returns for the enterprise; however, the positive externalities given by spillover effects result in increasing returns for the overall sector. In Romer's model, the (Cobb-Douglas 1928) production function becomes $Y = AK^\alpha(KL)^{1-\alpha}$, where α represents the quota of national per capita income destined to capital. The growth rate is constant, and this results in a permanent condition of steady state for the economy. Moreover, while an increase in knowledge will determine an immediate rise in the economy's growth rate, the boost of the savings quota destined to investment will permanently influence growth. Also in this case scenario, the investment in learning and new knowledge acquired by the entrepreneur will create positive externalities for the entire sector through the spillover effect, thus justifying policy interventions supporting innovation on the part of the State.

Human capital then assumes a central and relevant role in Lucas' model, where the emphasis is on the role of education as the only sector really capable of producing innovation. In his model, workers, for every unit of time, are asked to choose between work and education. Clearly, with the former option, they would benefit from a higher level of current income, whereas with the latter they would be able to improve their skills, thus obtaining higher productivity and income in

the future. Having defined H as total human capital, and h as the knowledge of a single worker, the following relation may be formulated: $H = hL$; if (u) represents the time a worker dedicates to the productive process, $(1-u)$ will subsequently be the quantity of time dedicated to education and training, so that the equation determining the accumulation of human capital is $\dot{H} = H\phi H(1-u)$, where ϕ is a scale parameter, whereas the production function including human capital is given by $Y = AK^\alpha(uH)^{1-\alpha}$. From these equations it can be concluded that human capital is, in particular, a function of the time dedicated to education and training and that its marginal productivity is constant. In terms of general macroeconomic equilibrium, it will be found that, once the steady state is achieved, the stock of physical capital, like production and other related variables in the model, will continue to rise at a rate equal to the endogenous growth in human capital.

The Role of the Public Sector in Economic Growth Models

In neoclassical growth models, the public sector holds a role of agent responsible for the exogenous stimulation of investment and the education and training of human capital. Barro (1990) built a growth model where the goods and services produced by the public sector are considered as production inputs for the public sector. In his model, goods are divided between three main categories:

- Private, rival, and excludable goods, produced by the public sector
- Public, non-rival, and non-excludable goods, produced by the public sector
- Goods produced by the public sector and subject to congestion, i.e., rival non-excludable goods, such as roads, water supply, and sewers

In the first model, where G refers to the public sector's aggregate expenditure, the very nature of the (private) goods that are produced results in the quantity of available inputs being equal to $g = G/n$, where n represents the total number of producers. The introduction of the public sector in the Cobb-Douglas (1928) production function

results in the following equation: $y = Ak^{1-\alpha}g^\alpha$, where returns of capital are assumed to be decreasing and the level of public expenditure to be fixed. Each agent adopts a production technology that combines capital and public goods provided by the State, where y , k , and g , respectively, represent product, physical capital, and productive public investment per worker. A specific assumption is that entrepreneurs, given a fixed level of public expenditure, will determine the quantity of private inputs (k) that will be employed.

If the government is looking to maintain a neutral balance, one potential financing methodology could be the introduction of a tax proportional to the quantity of outputs equal to $\tau = g/y$. The latter allows us to derive the condition of efficiency determined by a given quantity of goods produced by the public sector. In fact, since each goods unit requires an increased use of resources, the natural condition of efficiency will be given by $\partial y / \partial g = 1$, which would in turn imply $g/y = \alpha$. Under these assumptions, Barro and Sala i Martin (1992, 1997, 2004) demonstrates that the profitability of investment is independent of the economy's growth rate, which will instead be influenced by the quantity of services produced by the public sector. Moreover, with a constant τ (og/y), the model does not allow for periods of transition, but rather gives a growth rate equal, in each period, to the steady state's growth rate.

In conclusion, it is interesting to analyze the possible scenarios determined by the government managing to produce efficiently, thus respecting the condition $g/y = \alpha$. If marginal taxation (τ) is equal to zero, returns on investment, be it private or social, will be identical. However, in the case where $\tau > 0$, private returns will be lower, and a condition of Pareto efficiency may be achieved by employing a lump-sum form of taxation on consumption or through the introduction of a subsidy to the purchase of capital goods on the part of the government.

On the other hand, in the case where the public sector produces public goods as defined by Samuelson (1954), the production function is modified according to the introduction of the hypothesis of

non-rivalry in consumption. Consequently, the whole quantity G of each producer will be presented as opposed to the relative per capita quota, resulting in $y = Ak^{1-\alpha}G^\alpha$. Non-rivalry implies that the marginal product of public goods will be given by the effect of the variation in G on aggregate output $Y = y n$ and the corresponding condition of efficiency will be given at the point where $G/Y = \alpha$. Having taken into account these minor differences, the model maintains all the implications already presented in the case of the production of private, rival, and excludable goods.

However, different implications are given when the public sector produces goods that are subjected to congestion, in other words, being characterized by rivalry and non-excludability in consumption. The phenomenon of congestion derives from the difficulty of excluding enterprises from the consumption of a given rival good, which would thus be exhaustible. Thus, for a given level of production (G) of a good, each enterprise will see a decrease in the quantity available to it, as other enterprises increase their consumption of the said good. Consequently, the production function for each producer will include a relation between the total quantity of product G and the aggregate quantity of private inputs K ; therefore, $y = Ak (G/K)^\alpha$. Since the increase in capital (k) and in production (y) of a given enterprise congests the inputs (g) available to the remaining enterprises, in the absence of a proportional tax on outputs or on income, there will be an excessive consumption of “public” goods. The introduction of a tax equal to $\tau = G/Y$ will, on the other hand, be able to match the rate of returns on social and private investment, thus bringing about a Pareto optimal growth rate.

Modern Thought

While an increasing number of academics concentrated on formalizing and arguing in ever greater detail the role of human capital, education, technology, and innovation in economic growth, a group of economists, motivated by the certainty that the abovementioned elements do not constitute the engines of growth, but rather represent the consequences of the latter, set out to determine new variables that would result in being essential

for development. The said research brought them to the identification of a series of elements that may be defined as immaterial and consist in the role of institutions, regulations, faith, and cooperation within society.

Institutions and Economic Growth

According to Acemoglu (2008), institutions influence the growth trajectory. The first approach to this facet is attributable to North, who defined the concept of institutions as the rules of the game within a society or, more formally, the limits conceived by man to determine human interaction. First and foremost, it must be noted how North's definition of institutions moved away from that generally conceived in everyday language. Entities such as parliament, enterprises, universities, or associations are defined by the author as organizations and are thus considered agents for change. The key concept used as a determinant of growth is, in fact, the relationship and interaction between institutions and organizations. Since the latter are born and die as a response to the set of incentives and limits imposed by institutions, the understanding of the nature of the latter, as well as how they change, represents a key for the historical evolution of countries. When analyzing the role of institutions within the economic system, the level of cooperation is identified as being a fundamental element. By applying game theory to a neoclassical structure with limited rationality, North understood that the role of institutions consisted in the highest possible reduction of transaction costs in the exchanges between agents, with the aim of rendering them convenient and encouraging their diffusion. It is clear that the level of cooperation is inversely correlated to the number of existing institutions, since when there is knowledge of the different parts and of repeated exchange (high level of cooperation), each agent does not need to feel protected by formal regulations and thus does not consider the presence of institutions as necessary. On the contrary, when there are impersonal exchanges and a high risk of disloyal behaviors, institutions acquire a fundamental role in the reduction of information costs and in the control and implementation of agreements. In conclusion, it can be stated that

the quality of regulations (institutions) influences the level of production, through the diffusion of exchanges, and subsequently affects economic growth.

Another approach, which may be considered similar to North's, however more centered on the role of the State in the promotion of an efficient economic system, is that implied by Evans in his conception of the embedded autonomy. The latter describes an ideal condition that governs the relationship between the State and civil society. In "embedded" States, one would find public officials, and institutions in general, that are deeply intertwined with economic actors and dedicated to trying to understand and favor the interests of the latter. A rooted territoriality allows for the implementation of "fitted" policies aimed at fulfilling the competitive needs of enterprises, thus favoring their development and international competitiveness. Obviously, an excessive degree of embeddedness brings about the risk of a loss of authority and of impartiality. For this reason, the State must preserve its autonomy when the moment comes to take decisions, trying to avoid being a mere instrument for the satisfaction of individualistic interests and always preserving the collective well-being as its foremost objective. To sum up Evans reasoning, a simple comparative advantage in resources of a given country will not necessarily imply a success in the corresponding sector, but will rather depend on the functioning of the existing social and political institutions. If a wealth in resources is accompanied by a predatory State, which incentivizes renters and allows for widespread lobbying, thus losing the required autonomy in decision making, then development is unlikely to be achieved. On the other hand, a State that implements development policies and is characterized by the incentivizing of entrepreneurs, meritocratic recruitment, dedication, cohesion, and social loyalty will promote efficient and profitable investments on the part of enterprises, which will thus result in long-term growth and development.

Corruption and Economic Growth

The emphasis applied by North on the role of regulations in economic growth stimulated for

many economists an interest towards understanding how bureaucratic machines, with all their dishonesty and obstructive presence, are able to slow down the process through which technological progress transforms into new tools and productive processes.

Many theoretical and empirical articles in economic, social, and political literature have studied how corruption affects economic development. Their authors have mainly concentrated on the relationship between corruption and economic growth, not always finding coherent results. On the one hand, Leff (1964) and Huntington (1968) argued that corruption could be positively correlated to economic performance in the presence of a thick and cumbersome bureaucracy. According to their reasoning, bribery may allow firms to get things done, thus increasing their efficiency and enhancing economic growth. Subsequently, corruption could be considered as growth enhancing in that it acts as a lubricant within a rigid bureaucracy. On the other hand, corruption can be seen as a type of government inefficiency, since it discourages investments, due to the wide discretionary power of public officials, as well as reducing the quality of public infrastructure and services, decreasing tax revenue, and affecting the allocation of entrepreneurial skills, thus slowing down economic growth (Bardhan 1997; Mauro 1995, 1998). Specifically, corruption diverts the public budget destined to social services, securities, and education, health, and general services. This implies inefficient behavior on the part of the government, in its implementation of policies that are not always in the country's best interest (Powell 2004). The market allocation of resources is thus distorted, negatively influencing investments on the part of economic agents, reducing the quality of public infrastructure and services, and thus hindering economic growth (McMullan 1961; Tanzi and Dawoodi 1997; Mauro 1995). In addition, corruption affects both the total regional amount of public spending and its structure, directing expenditures towards sectors where bribes are easier to collect. In this respect, the econometric results found by Del Monte and Papagni (2007) on the Italian regional dataset "show two distinct negative effects of

corruption on economic growth. One effect seems to be that on private investment; the other is on the efficiency of expenditures on the part of public investment.” It is therefore derived that “policies to deter corruption and to increase the efficiency of local public institutions could give very positive impulses to economic growth” for the development of southern Italy.

Social Capital and Economic Growth

Within the field of study related to the immaterial aspects of economic growth, the main contributions are undoubtedly given by J. Coleman and R. Putnam, both of whom consider social capital as being an engine of growth. Despite the lack of an unequivocal and widely accepted definition of social capital, it can certainly be distinguished from the concept of human capital, given that it is related to the set of social relations available to a subject or a group of subjects. At the core of this definition is the relational element. From the latter, in fact, one can derive the definitions of three different conceptions of social capital. The first one links social capital to the idea of members of a collective adhering to shared regulations; the second identifies it as the ability of a single subject to activate and manage interpersonal relations; and the third one associates it to the individual’s capability to create networks that are useful for the achievement of one’s own objectives. From these definitions it can be inferred that social capital and institutions are two inversely correlated subjects. The higher the presence of social capital, the lower will be the need for institutions in terms of guarantor for the implementation of agreements, since social sanctions will play a more prominent role. Within this framework, Coleman’s approach is based on the neoclassical assumption of full rationality, however considering each economic agent, not individually, but as a part of a network of relationships. In the latter, there will be certain leading individuals that will impose their own rules; thus, the social relations between the subjects constituting the network will be the only leverage they will have to condition the approval and implementation of norms in their favor.

Putnam’s work, on the other hand, can be traced back to the function of social capital as

a determinant of the difference in growth between countries (Alfano and Baraldi 2012). In other words, he is interested in the analysis of the existence of loyalty and of ethical norms of reciprocity and cooperation, as a tool for analyzing the role that interpersonal relations can play in different countries’ experiences of growth.

The most important empirical contribution made by Putnam is summarized in his work “Making Democracy” (1993), which develops a comparative study of Italian regions, attributing the divergence in institutional and economic performance between the North and the South to the differences in their relative endowment of what he refers to as social capital. In fact, northern Italy developed faster than southern Italy because the former has been better endowed with social capital. Considering “a region’s chance of achieving socioeconomic development during this century has depended less on its initial socioeconomic endowments than on its civic endowments, [the] correlation between civics and economics reflects primarily on the impact of civics on economics, and not the reverse” (Putnam 1993, p. 157). In conclusion, Putnam takes into consideration a historical path dependency, according to which “social patterns, plainly traceable from early medieval Italy to today, turn out to be decisive in explaining why, on the verge of the twenty-first century, some communities are better able than others to manage collective life and sustain effective institutions” (Putnam 1993, p. 121) that promote economic growth.

Within this same field, Fukuyama’s study on trust has contributed to the increased attention to the relevance of social capital in economic growth. According to Fukuyama (1995), societies endowed with generalized trust enjoy a form of social capital that, together with traditional factor endowments such as labor and capital, contributes to their success in modern economic competition. From this conception of the role of loyalty, it can be observed that countries with an elevated endowment of social capital are differentiated by the presence of a great enterprise, while those with only a low level of social capital are characterized by a productive structure dominated by small enterprises, where both ownership and

management are family based. The author thus marks a red line between social capital, family, loyalty, and a country's ability to generate capital and utilize it in large-scale investments. In a society with little faith in those outside the family, one would encounter what is known as familism, a phenomenon that leads the family to close itself off, thus hindering relations with the wider community. The said community may be viewed as the perfect equilibrium between the excessive isolation of the family on the one hand and the disproportionate presence of the State on the other, which discourages action on the part of spontaneous groups. According to the author, it is between these two identities that social capital and trust based on shared values are built, thus creating the expectation of a correct behavior and allowing for the birth of great organizations with evolved systems of management control.

Last but not least, reference should be made to the economist Amartya Sen, who, in his work *Development as freedom*, highlights the inappropriateness of the indicator of economic growth as a proxy for the real well-being and economic progress in a society, thus providing the decisive impulse towards its abandonment, in favor of new measures of development. He highlights how economic growth is closely connected to a function of social well-being that is highly utilitarian and that does not take into account the distribution of wealth but only its total amount. By relegating the concept of economic growth to such an index, there is the risk of paradoxically considering as blossoming economies, those found in countries where there is a rapid increase in production on the one hand and a complete absence of other important elements on the other, such as freedom and life expectancy, the opportunity to escape avoidable illnesses, the possibility of finding one's desired employment, and to live in a peaceful society free from crime.

The importance of these elements in the economic growth of countries has become clear and widely accepted among economists. Even a portion of the current entrepreneurial class seems to have understood the importance of adopting policies that allow for corporate growth in a more socially friendly manner. The latter can

explain the ever-increasing implementation of corporate social responsibility (CSR) policies and social balances that highlight ethical behavior and attention to social issues on the part of the enterprise, with the aim of developing a more beneficial image both at local and at international level, thus subsequently generating higher profits. The application of this concept in balances and national policy strategies represents, without a doubt, the current frontier of the concept of economic growth. Indeed, in July 2010, the European Commission officially committed to a new policy towards sustainable and equitable development, centered on the very concept of CSR. The said policy has been named Europe 2020 Strategy and consists in a series of interventions for long-term economic growth, social cohesion, and environmental safeguard. The financial crises that started in 2008 highlighted the inappropriateness of the growth models that had thus far been followed by most states. With the aim of closing the gaps found in the said growth models and creating the preconditions for a different, smarter, more sustainable, and equitable type of development, a document has been developed describing key objectives to be achieved by 2020. The latter may be summarized as follows: with regard to labor, the goal is to increase by 75% the rate of employment for those aged between 20 and 64 years old; for research and innovation, the aim is to increase by 3% of the EU's GDP the investments in research and development; as for the safeguarding of the environment, the objective is to reduce greenhouse gas emissions by 20% compared to 1990, as well as increasing by 20% the supply of energy coming from renewable resources; with regard to education, the target is the reduction in school dropout rates by 10% and to increase by 40% the 30–34 year olds with higher education; finally, in the fight against poverty and marginalization, the European goal is to reduce by 20 million the number of inhabitants at risk of, or already living in, poverty. It is interesting to point out that current European policies on growth still contain a great portion of the economic thought analyzed above, specifically when it comes to theories on human capital, on the importance of research and development, and

on social responsibility. It should thus be noted that there is still a significant lack in policies aimed at developing social capital, and improving the quality of institutions, and that only in 2010 actions were taken towards the modification of growth models according to economic theories that had been formulated and proven years before. This institutional delay in embracing the suggestions transmitted by academics and researchers should, therefore, be taken into account as an important variable in future developments of models of economic growth.

Economic Impossibility

► Impracticability

Economic Integration

George Tridimas
Department of Accounting, Finance and
Economics, Ulster University Business School,
Belfast, Northern Ireland

Abstract

Economic integration is the establishment of a unified economic area where consumers and producers of different nations transact freely in a single market. Using the experience of the European Union, this essay offers a bird's-eye view of the trade-offs encountered when supranational structures pursuing collective objectives of integration may infringe on national sovereignty. The range of issues examined include: (A) Determination of policy with multiple veto players. (B) The advantage and disadvantages from centralising policy making. (C) The welfare effects of a customs union from changing the flows of trade and factors of production across different

countries. (D) The costs and benefits from adopting a single currency and its consequences for budgetary policy.

Definition

Economic integration is the creation of a unified economic area where firms and consumers from different nations buy and sell goods and services in a single market and owners of capital and labor can deploy their resources in any economic activity anywhere in the area. Integration encompasses economic, political, and legal dimensions that overlap with each other. Our understanding and assessment of economic integration is inextricably linked to the experience gained from the establishment, geographical expansion, and extension of functions of the European Union (EU). Its development has been extensively researched in economics, political science, international relations, organizational sociology, and law. The present essay does not aim to survey any part of this enormous literature.¹ Rather, it offers some pointers on the issues regarding the following issues: setting up of supranational structures that pursue collective objectives but in so doing may encroach on national sovereignty, determination of policy with multiple veto players, centralization of policy making, market competition, trade effects of a customs union, factor mobility, and adoption of a single currency, monetary and budgetary policy.

European Economic Integration

The construction of the EU started after the end of Second World War and is ongoing. Table 1 presents a brief timeline of landmark events in the development of the EU. To complete the

¹For textbook expositions, see amongst others Senior Nello (2011), Baldwin and Wplosz (2012) and Saurugger (2013). Detailed analysis of monetary integration can be found in Issing (2008) and De Grauwe (2012). The interested reader is also referred to the papers in the volume edited by Artis and Nixon (2007).

Economic Integration, Table 1 The evolution of the EU at a glance

1952	Belgium, France, Italy, Luxembourg, the Netherlands, and West Germany form the European Coal and Steel Community
1957	The six sign The Treaty of Rome, forming the European Economic Community (EEC) and the European Atomic Energy Community (Euratom)
1966	The Luxembourg Compromise is accepted, permitting member states to demand legislation to be adopted by unanimity when very important interests are at stake
1967	The three communities are united as “European Communities”
1973	Britain, Ireland, and Denmark join
1978	The European Monetary System and the European Currency Unit are founded
1981	Greece joins
1986	Spain and Portugal join
1986	The Single European Act is adopted, creating the Single Market
1990	Eastern Germany joins after the German reunification
1992	The Maastricht Treaty is signed, creating the European Union
1995	Austria, Sweden, and Finland join
1997	The Amsterdam Treaty is signed, amending the Maastricht Treaty
1998	The European Central Bank (ECB) is set up
1999	The <i>euro</i> currency is created by irrevocably locking the exchange rates of participating countries and monetary policy making is transferred to the ECB
2000	The Treaty of Nice Treaty is signed, amending earlier Treaties
2002	The <i>euro</i> ” becomes the sole currency of 12 out of 15 members (Britain, Sweden, and Denmark retain their national currencies)
2004	Poland, Hungary, the Czech Republic, Slovakia, Slovenia, Latvia, Lithuania, Estonia, Malta, and (the Greek part of) Cyprus join
2004	The Treaty of Rome establishing a constitution for Europe is signed
2005	Dutch and French voters reject the 2004 Constitutional Treaty; EU leaders suspend its ratification
2007	Bulgaria and Romania join
2007	The Treaty of Lisbon is signed, amending the Treaty on European Union and the Treaty establishing the European Community
2009	The Treaty of Lisbon enters into force after its ratification is completed
2013	Croatia joins

economic union, a number of intermediate stages must be accomplished:

1. Duty-free access to each other nation’s market, which requires the abolition of tariffs and non-tariff restrictions on trade between the member states.
2. Implementation of a common tariff on trade with non-member states to prevent cheaper imports entering the market through members states with lower external tariffs, known as a customs union.
3. Establishment of a free market in goods and services among the member states to ensure competition; this requires the harmonization of national laws and practices that regulate the market (including the relevant taxes), the abolition of anticompetitive structures, and the prohibition of state aid or other preferential treatment by member state governments to national firms.
4. Establishment of a free market in labor and capital, which is achieved by eliminating discriminatory treatment of workers on the basis of nationality, granting firms the right to establish in another member state and the removal of restrictions on capital flows.
5. Establishment of a monetary union where the member states adopt a single currency, so that prices and trading in the single market will not be affected by national currency fluctuations; in turn a single currency requires establishing a union-wide central bank to conduct monetary policy.

Each successive stage envelops its predecessor. Not all member states participate in the monetary union, with Denmark, Sweden, and the UK deciding to keep their national currencies, while countries that entered the union after the launch of the euro are expected to adopt the currency when their economies are ready to do so. A further step, one yet to be taken by the EU, is the fiscal union where taxes and transfers are decided centrally. It is however noted that contrary to the above checklist, the EU has adopted a protective agricultural policy. Each successive step implies a certain loss of national sovereignty, for example, a common tariff prevents a country to decide its own external trade policy or, with a common currency, a country can no longer implement an independent monetary policy.

Institutions of EU Governance

After the horrors of two world wars in a space of 20 years, the European economic integration was conceived as a form of international organization to bind together rival European powers, especially France and Germany, in order to prevent another war. That is, economic means were used to accomplish a political objective. What followed was a series of international treaties that over time established an intricate system of Europe-wide governance (control of decision making), changed the scope of national legislative powers, and created a body of legal acts and court decisions (known as the *acquis communautaire*) by which all member states abide, while on the economic side, it has shaped industry structures, labor market, trade, investment, and monetary flows.

Establishment of the EU by independent states meant the voluntary “pooling of sovereignty” to promote common interests and international public goods, like peace and prosperity, which are best pursued jointly rather than individually by each country. This also necessitated setting up bodies of collective decision making to pursue the common objectives and simultaneously governance mechanisms to check that the new bodies will act within the agreed limits without infringing on the rights of their creators. The main

institutions established to drive and administer the process of integration are the following.

The European Council which consists of the leaders of the EU countries sets the EU’s general political direction and priorities and deals with complex and sensitive issues that cannot be resolved at a lower level of intergovernmental cooperation. It meets four times a year and is chaired by the President of the European Council. The President of the European Commission and the EU’s High Representative of the Union for Foreign Affairs and Security Policy also take part in the meetings. The decisions of the European Council are taken by unanimity or by qualified majority, depending on what the EU Treaty provides for. Though influential in setting the EU political agenda, it has no powers to pass laws.

The Council of the European Union (not to be confused with the previous European Council), also informally known as the EU Council, or Council of Ministers, which brings together national ministers from each EU country to pass EU laws coordinate the broad economic policies of EU member countries, sign agreements between the EU and other countries, approve the annual EU budget, develop the EU’s foreign and defense policies, and coordinate cooperation between courts and police forces of member countries. As a general rule, the Council of the EU decides by qualified majority voting. From November 2014 a system known as “double majority voting” will be introduced. For a proposal to go through, it will need the support of 2 types of majority: a majority of countries (at least 15) and a majority of the total EU population (the countries in favor must represent at least 65% of the EU population). A blocking minority must include at least four Council members; if the latter fails, the qualified majority shall be deemed attained. When sensitive issues are decided, for example, security and external affairs and taxation, decisions have to be unanimous rendering veto powers to every single country. The Council of the EU represents the interests of the national governments of the member states.

The European Commission, which proposes policy measures, manages the day-to-day business of implementing EU policies and spending

EU funds and represents the EU internationally. It is an executive supranational body that represents the Community interests. It consists of 28 Commissioners, one from each country serving for a renewable term of 5 years. The President and members of the Commission are appointed by the European Council.

The European Parliament, which in an embryonic form, represents directly the interests of the peoples of Europe. Its role is to debate and pass laws in combination with the Council, debate and adopt the budget of the EU, and scrutinize other EU institutions. Its members are directly elected for terms of 5 years. Their number is 751 including its President; there is a minimum threshold of 6 members per country and a maximum of 96 (implying that smaller countries weigh higher in its composition). The members are grouped according to political affiliation and not by nationality. In comparison with national parliaments, it has significantly fewer legislative powers, but its powers have increased dramatically over time. It decides by simple majority.

The Court of Justice, whose task is to examine the legality of European Union measures and ensure the uniform interpretation and application of the EU law. It consists of one judge per EU country and eight "Advocates-General" whose job is to present opinions on the cases brought before the Court. Its members are appointed upon the common accord of the governments of the member states for renewable six-year terms. By far the largest part of the workload of the ECJ is to hear direct actions and give preliminary rulings. Direct actions concern violations of the EU law and include enforcement actions, where the Court declares whether or not a member state has infringed or complied with EU law; actions for judicial review, where the Court may annul an act of an EU institution for violating the EU law or for failing to make decisions required of them; and actions for damages, where the Court may determine the liability of an EU institution. In preliminary rulings, the Court on the request of a national court interprets a point of the EU law; this way it ensures the uniform interpretation of EU legislation.

The European Central Bank has been set up to manage the euro and maintain price stability in the

EU. More specifically, its tasks are the determination and implementation of monetary policy by setting key interest rates for the 17 countries that currently use the euro as their currency (Austria, Belgium, Cyprus, Germany, Estonia, Greece, Spain, Finland, France, Ireland, Italy, Luxembourg, Malta, the Netherlands, Portugal, Slovenia, and Slovakia), the conduct of foreign exchange operations, the holding and management of the official foreign reserves of the euro area countries, and the promotion of the smooth operation of payment systems. The ECB is also responsible for framing and implementing the EU's economic and monetary policy. It is politically independent of the governments of the member states.

In comparing the role of the nation-states vis-à-vis that of the supranational bodies established to pursue and administer the objectives of European integration, two competing schools of thought appeared, namely, intergovernmentalism and supranationalism. Intergovernmentalism argues that the process of integration is controlled by the national governments of the member states which impose the policies that best suit their interests; hence, the institutions of international governance set up by the Treaties serve the purposes of their creators, usually the most powerful of the founding states, like France and Germany. On the contrary, supranationalism, or federalism, argues that economic integration, exchange, and cooperation across national borders generated a new transnational community whose interests are best served by setting institutional structures with some autonomous policy-making powers previously reserved for the nation-state.

Determination of Policy with Multiple Veto Players

The previous description of the governance organs makes clear that policy making in the EU is a complicated matter involving the strategic interaction of multiple players, where strategic means that the action of an actor takes into account the expected response of another actor whose interests are affected by such actions. The

interests of the national and supranational actors may not necessarily coincide on all issues at hand, whereas only the Commission has agenda-setting powers to initiate legislation, and decisions are subject to the veto power of the Council, the Parliament (a process known as co-decision), and, as practice has shown, the Court.

The qualified majority voting rule used by the EU (in approximately 80% of all its decisions) in combination with its supranational character raises a host of important issues. The first regards efficiency in decision making, which relates to how easy it is for the EU as a collective group to take a decision. It refers to how likely is to find a majority given the specific voting rule and the distance between the policy preferences of the national and supranational actors. In general the answer to that depends on the required majority, the number of countries, and the weight (number of votes) of each country. The second issue relates to the distribution of power among member states is approximated by the weight awarded to each member state in the Council of Ministers. In the EU, the countries with small populations, like Luxembourg, have been given greater weights than the more populous countries, like Germany. This goes a long way to explain the observed pattern of EU spending in favor of less populous countries. The third issue regards legitimacy of the EU. A decision is accepted as legitimate when it is accepted that the decision maker has

the right to take that decision. At one extreme, if the EU is considered as a union of states, as in a confederation, then legitimacy requires one vote per state. At the other extreme, if it is a union of peoples, then legitimacy requires equal power per citizen entitling more populous countries with increasing voting weight in the Council. Historically, the union-of-the-peoples approach has been the EU norm since more populous states have a larger voting weight.

Centralization Versus Decentralization of Policy Making

Economic integration requires that some policies are decided by the supranational institutions, “the central authority,” and a common policy applies to all member states. Examples include external tariff, market competition, environmental protection, arguably, monetary policy (if a single currency is adopted), financial regulation, and even some aspects of budgetary policy. This “harmonization” of policy opens up the debate of the merits of centralization versus decentralization. When the member states have different preferences for those policies but are forced to consume a greater (or smaller as the case may be) level of the service than it would have been optimal given their preferences when acting independently, a welfare loss results. This is depicted in Fig. 1 which shows the

Economic Integration,

Fig. 1 Diversity of preferences, economies of scale, and welfare of centralization

demand for a public service by two countries 1 and 2 and D_1 and D_2 , respectively, when the supply (marginal cost) of provision is C . Under decentralization the two countries act independently and consume Q_1 and Q_2 corresponding to the intersection of demand and supply. When they form a union, the central authority equates average demand to supply and provides the same quantity Q_E to both 1 and 2. Since $Q_1 < Q_E < Q_2$, that is, country 1 overconsumes and country 2 underconsumes the public service, centralization generates the welfare losses measured, respectively, by the decrease in consumer surplus EB_1E_1 and EB_2E_2 . Such losses depend on the diversity of preferences and the elasticity of demand (the distance between the demand curves and their slopes). Had the central authority the relevant information about the different preferences in the two countries, it would have been able to provide them with the individually optimal levels of the service; in the latter case, however, there would be no reason to form a union and centralize policy making.

A second argument in favor of decentralization relates to the political benefits it offers. Specifically, citizens of independent states can choose their own government, so that they have the incentive and opportunity to make informed decisions about policies that affect them and they exercise more effective control over the discretionary powers of politicians. This way the political principal-agent problem is mitigated and accountability of politicians to voters is improved. In response to this issue, the EU has adopted the principles of *subsidiarity* and *proportionality*. Subsidiarity means that a policy is assigned to the supranational (=central) authorities when it cannot be achieved by the national authorities. According to proportionality, the content and form of the EU action shall not exceed what is necessary to achieve the objectives of the Treaties.

By contrast, the arguments in favor of centralization underline the benefits from economies of scale, correction of externalities, and elimination of inefficient noncooperative behavior. Centralization often involves significant economies of scale where increasing all inputs by the same proportion increases output more than

proportionally and costs rise more slowly than production, resulting in important gains for the consumer. Graphically, the presence of economies of scale that are exploited under centralization yields a supply curve at C' , lower than C . The new equilibrium obtained by the intersection of C' and is denoted by point N yields a larger equilibrium quantity for the two countries $Q_N > Q_E$. The gains from cost savings for countries 1 and 2 are shown, respectively, by the areas CB_1G_1C' and $CB_2N_2F_2$ and the corresponding losses from over- and underconsumption are represented by the triangles NN_1G_1 and NG_2N_2 . Thus, the net welfare gains from centralization for 1 and 2 are given by the differences $CB_1G_1C' - NN_1G_1$ and $CB_2N_2F_2 - N_2G_2N$.

Centralized decision making is also better equipped to address problems of positive or negative externalities (or spillovers), that is, situations where actions taken in one country (like burning fossil fuels or fishing) may increase or decrease the welfare of another country. However, the presence of externalities does not necessitate centralization, since such problems can be addressed by cooperation between the parties concerned. A third argument in favor of centralization is its ability to avoid noncooperative behavior by different countries. Countries competing against each other to attract business and mobile factors of production in their territories, which in turn increase the tax basis, may engage in games of competitive tax rate reductions (or other cost-cutting incentives, like relaxation of health and safety standards at the workplace) ultimately resulting in lower taxes and lower welfare in what is referred to as a "race to the bottom," that is, the lowest tax rate or protection for the workforce.

Trade and Growth Effects of Economic Integration

The economic rationale of integration among sovereign nations is that it promotes trade and growth and hence it increases welfare. In the short run, abolition of trade barriers allows economies to specialize according to their comparative

Economic Integration,
Fig. 2 Trade and welfare
 effects of a customs union

Net welfare effect of preferential trade: $ACF + BEG - HJGF$

advantage which increases the volume of trade; however, against such benefits, one must set the costs from trade protection measures against non-members. These static effects of economic integration for an importing country are sketched in Fig. 2.

The lines D_D , S_D , and P_W denote, respectively, the domestic demand for the imported good, the domestic supply, and the world supply at the exogenously given P_W price. When the country applies a tariff to imports from all countries, the domestic price rises to P_T ; domestic supply and demand are shown by OQ_1 and OQ_2 , imports by Q_1Q_2 , and import expenditure by Q_1HJQ_2 . When a trade union is formed with a partner country that excludes other countries, domestic supply is represented by the line $S_D + S_P$ and equilibrium is obtained at E where D_D intersects $S_D + S_P$. Domestic demand rises to OQ_4 , and domestic supply falls to OQ_3 , implying the larger Q_3Q_4 volume of imports. Consumer welfare has increased by the sum $ACF + BEG$; this represents the gain from lowering the import price and is known as the trade creation effect. However, the Q_1Q_2 imports now enter the country at the P_P rather than P_W price paid to the partner country implying that the expenditure on Q_1Q_2 is $HJGF$. This is known as the trade diversion effect. Thence, the net welfare effect of forming the union is $ACF + BEG - HJGF$, which can be positive or negative. In other words, it is not a priori clear whether the preferential trade

arrangement will benefit or harm the country members.

The effect of factor mobility is shown in Fig. 3 using the example of capital mobility. Assume again a two-country setting, where the capital endowment of countries 1 and 2, respectively, are O_1K_0 and K_0O_2 (giving a total capital stock of O_1O_2 as shown on the horizontal axis). Lines MPK_1 and MPK_2 show the marginal productivity of capital in the two nations (or, equivalently, the national demand for capital functions), and R_1 and R_2 show the return on capital in the two countries before capital market integration, with $R_1 > R_2$. The areas defined by the MPK curves, the axis and the individual capital endowments, $O_1A_1B_1K_0$ and $O_2A_2B_2K_0$, show the outputs of countries 1 and 2, respectively. $A_1B_1R_1$ and $O_1R_1B_1K_0$ represent the sizes of labor and capital income in country 1, and $A_2B_2R_2$ and $O_2R_2B_2K_0$ show the corresponding magnitudes in country 2. When capital markets are integrated, capital flows freely from the low-return country 2 to the high-return country 1 until returns are equalized at R^* at the intersection of MPK_1 and MPK_2 ; country 1 ends up using domestically capital O_1K^* (although it owns OK_0), total output equal to $O_1A_1EK^*$, and labor income A_1ER^* (higher than before by $R_1B_1ER^*$). In country 2, output falls to $O_2A_2EK^*$, labor income falls to A_2ER^* , and capital income rises to $O_2R^*CK_0$ (upon adding the capital earnings from capital owned by country 2 but used in 1). Thus, the net effect of integration is again

Economic Integration,
Fig. 3 The effects of factor
mobility

represented by B_1EB_2 , which is the sum of the extra labor income in country 1, B_1EC , and the extra capital income in country 2, B_2EC . Clearly, although the overall integration has a positive effect on welfare, it creates winners and losers in each country, who may resist it with various degree of success depending on their political influence. Similar conclusions about increased output and its differential distribution are derived when we consider the labor market and allow immigration from a low-wage to a high-wage country.

Over the long run, integration implies that firms have access to a larger union-wide market and that they face stiffer competition than when they were confined to their national market only. As a result of more competition, costs and profit margins are squeezed and prices fall. Firms that survive become bigger and better able to exploit economies of scale driving prices further down to the benefit of consumer. The benefits of the restructuring process, however, are at risk from two sources. National governments bowing to political pressures may subsidize and otherwise assist failing firms, delaying the efficient restructuring of the economy. Secondly, the emergence of fewer but bigger firms may lead to price collusion, negating the benefits of lower prices for consumers. It is for these reasons that the EU has

introduced strict rules forbidding state aid and enforcing competition. Since integration encourages a more efficient allocation of resources, human and nonhuman, labor and capital are allocated more efficiently across different countries, boosting the rate of economic growth.

Monetary Union

Monetary union or monetary integration is an arrangement between participating countries where the exchange rates are permanently and irrevocably fixed, so that a single currency can be used by all members. Several benefits are associated with the adoption of a single currency:

- The elimination of exchange rate fluctuations and the ensuing uncertainty which discourages trade and investment.
- Reduction in transaction costs relating to conversion fees and commission charges incurred when exchanging different currencies.
- Seignorage gains from establishing the single currency as an international reserve currency; these arise from the willingness of the rest of the world to hold the single currency as an asset which then allows the monetary union to import more than it exports.

- (d) Reduction in the opportunity cost of keeping foreign reserves, since the union needs fewer reserves to manage its currency than the sum of reserves needed by each member state acting independently.
- (e) Greater effectiveness in pursuing aggregate stabilization policy. While many small open economies acting on their own cannot implement successful short-run aggregate demand management policies because of their dependence on international trade, a union can succeed by coordinating policy among member states.
- (f) For countries characterized by high inflation before the formation of the monetary union (like Italy and Greece), adopting a single currency managed by a central bank which is committed to price stability introduces a credible anti-inflationary assurance (or so the argument ran before the debt crisis of 2010).

However, such benefits may be accompanied by severe costs: giving up monetary policy independence and adopting the single currency imply that a country can no longer use the exchange rate to counteract demand and/or supply shocks. When domestic prices and wages are slow to adjust to such shocks, the exchange rate can be used to adjust domestic demand and supply to reestablish macroeconomic equilibrium quickly. With a floating exchange rate system, the exchange rate will adjust to maintain balance of payments equilibrium; monetary policy becomes effective to affect the domestic economy, but fiscal policy becomes ineffective (because capital will move in and out of the country responding to domestic and foreign interest rate differentials). On the other hand, under a fixed exchange rate regime, the authorities must respond to a surplus by reflation and to a deficit by deflation; thus, monetary policy becomes ineffective, while fiscal policy is now effective. These considerations point to the “impossible trinity” of having simultaneously a fixed exchange rate, independent monetary policy, and perfect capital mobility.

Whether or not a group of countries will benefit from forming a monetary union has been

examined by the “optimum currency area” (OCA) literature. This starts from the observation that the larger the area using the same currency, the larger its benefits; but as the area grows larger, it includes more diverse countries, which increases the costs of using the currency. Specifically, in the face of an adverse external shock that affects different countries differently (small economic losses for some but large for others), a single central bank cannot differentiate its policy responses according to the needs of the different countries. Asymmetric costs may deter the formation of a currency union. A group of countries can form a successful OCA when the following conditions are satisfied: (a) The labor force is mobile across the different countries. (b) The countries have diversified economies and produce and export similar goods. (c) The countries are open to international trade with each other. (d) They have adopted a mechanism of fiscal transfers that compensate each other for adverse economic shocks. (e) They share common preferences on how to respond to an external shock. (f) Perhaps more importantly, since none of the previous criteria may be fully satisfied, the countries have a sense of solidarity that their fates bound them together and so accept the costs of asymmetric shocks.

When countries lose the exchange rate as a policy instrument, they can use fiscal means to counteract any adverse shocks to aggregate demand, especially if fiscal transfers are not feasible (see (d) above). Despite the efficacy of discretionary fiscal policy in a system of fixed exchange rates, its use by member states of an economic union with a single currency is controversial. Acting independently, a member state running persistent large budget deficits adding to national debt may lead to severe difficulties. To bail out the highly indebted country, the central bank may increase the money supply, bringing inflation and depreciation of the single currency. Alternatively, debt accumulation may lead to higher interest rates for all country members crowding out private investment. If capital markets are efficient and assess the default risks of different governments, they will demand significantly higher interest on the debt of the profligate

government without a general interest rate increase. But if high indebtedness leads to fears about the financial stability of other countries, the commitment of the central bank to low inflation may no longer be believed, implying that the policy of no bailouts for fiscal profligacy lacks credibility. Accordingly, the risk of default is lower than otherwise. This generates a moral hazard problem where a member has an incentive for spending profligacy. Note that there may even be an adverse selection problem where only the worst offenders (those who run the biggest budgetary deficits, like Italy and Greece) are interested in joining the monetary union.

Economic Performance

Marianna Succurro

Department of Economics, Statistics and Finance,
University of Calabria, Rende (CS), Italy

Abstract

Economic performance indicates the way in which a country or a firm functions, that is the efficiency with which they achieve their intended objectives. Alternative approaches to measuring both macroeconomic and microeconomic performance exist. Gross Domestic Product, among others, is one of the most important indicator to know how well an economy is performing and, given the existence of international standards for its calculation, it is also widely used across the world for international comparison. Efficiency and productivity, as well as long-term growth, are traditional indicators of firm performance. It is important to note, however, that all indicators are imperfect and, overall, it is important for economists and policy makers to look beyond the headline statistics to give a better overall picture of economic welfare.

Definition

Economic performance indicates the way in which an economy functions. In general, it signals the efficiency with which a country or a firm achieves its intended purposes.

What we intend to measure

...Every day, in every industrialized country of the world, journalists and politicians give out a conscious and unconscious message. It is that better economic performance means more happiness for a nation. This idea is rarely questioned... (Oswald 1997)

A prerequisite for examining alternative approaches to measuring economic performance

is an agreement on precisely what we intend to measure. This objective is closely related to the goals that societies and, hence, policy makers want to pursue. However, there is little doubt that economic policy makers need regular, timely, and accurate indicators of economic performance which, on the other hand, can relate to both countries (macroeconomic performance) and firms (microeconomic performance).

Measuring Macroeconomic Performance

The performance of an economy is usually assessed in terms of the achievement of economic objectives. These objectives can be long run, such as sustainable growth and development or short term, such as the stabilization of the economy in response to sudden and unpredictable economic shocks.

In general, to know how well an economy is performing, economists employ a wide range of economic indicators. Economic indicators measure macroeconomic variables that directly or indirectly enable economists to judge whether economic performance improves or deteriorates. Tracking these indicators is especially valuable to policy makers, both in terms of assessing whether to intervene and whether the intervention has worked or not.

Traditionally, the key measures of macroeconomic performance include:

1. Levels of real national income, spending, and output, three key variables that indicate whether an economy is growing or in recession. Like many other indicators, they are usually measured in per capita (per head) terms.
2. Economic growth, real gross domestic product (GDP) growth, GDP per capita.
3. GDP per hours worked as a measure of economic productivity, labor productivity.
4. Price levels and inflation.
5. Employment rate for the 15–64 age group and patterns of employment.
6. Unemployment levels and types.
7. Current account – satisfactory current account (e.g., low deficit).
8. Balance of payments.
9. Final consumption expenditure per capita, including government consumption.
10. Income inequality.
11. Investment levels and the relationship between capital investment and national output.
12. Levels of savings and savings ratios.
13. Competitiveness of exports.
14. Trade deficits and surpluses with specific countries or the rest of the world.
15. Debt levels with other countries.
16. The proportion of debt to national income.
17. The terms of trade of a country.
18. The purchasing power of a country's currency.
19. Wider measures of human development, including literacy rates and health-care provision. Such measures are included in the Human Development Index (HDI).
20. Measures of human poverty, including the Human Poverty Index (HPI).

Gross Domestic Product (GDP)

GDP is one of the most important indicators of economic performance. Since there are international standards for its calculation, it is also widely used across the world for international comparisons.

As GDP is a measure of a country's overall production for any given year, it is a reliable, albeit still imperfect, gauge of a country's economic performance. This is the justification for the great attention which both the general public and policy makers pay in all advanced economies to the regularly published GDP figures.

GDP, however, has several limitations.

Firstly, GDP doesn't take into account income distribution, since it could primarily benefit the top income strata of the population.

Secondly, it is characterized by well-known deficiencies related to the measurement of economic activities. Indeed, various nonmarket outputs, such as household activities and services provided free of charge, are systematically overlooked. The underground economy is difficult to capture, particularly certain criminal activities, although several attempts have been made to

harmonize the coverage of the underground economy at EU level in order to obtain comparable GDP measures. Some elements of GDP are fragile estimates, particularly those of the volume of publicly provided services and of the quality incorporated into products. Finally, some expenditures are unequivocally counted as positive contributors to economic performance, while the negative externalities associated with them – such as environmental damage – are neglected. As a result, GDP understates output.

Finally, even if GDP is a measure of market production, it has often been treated as if it were a measure of economic well-being. The measurement of GDP, however, does not address all aspects which are relevant for the material well-being of an economy; thus, it is not always a reliable guide to living standards. While the general public and many policymakers regard GDP as a measure of material well-being, this interpretation ignores the fact that production is not the ultimate goal of a society. In this context, production-based measures need to be complemented by a broader set of indicators if the aim is to assess well-being. These additional indicators would include social investment like infrastructure, education, access to health care, housing, as well as quality of life like material wealth, mental state, stress, perception of crime, environment, etc. Conflating GDP and well-being can lead to misleading indications about how well-off people are and entail the wrong policy decisions.

Making GDP a Better Measure of Economic Performance

Economic policy makers unquestionably need an economic performance indicator for short-term decision-making. Macroeconomic policy frequently operates with a time horizon of 1–2 years and, from this perspective GDP, as an indicator of current value added, is arguably the most informative gauge of economic performance. However, even in this area of economic policy, it is necessary to go “beyond GDP” by analyzing data on unemployment, inflation, short-term business activity, and consumer or business sentiment.

Although the usefulness of GDP is limited from a medium-term perspective, it still remains a viable indicator of medium-term performance. Thus, in conceptual terms, GDP remains the cornerstone of economic performance assessments. Nevertheless, it should be improved in various directions.

The most important starting points for improvements are (i) improving the measurement of service output in general and of government services in particular and (ii) making progress in measuring quality improvements.

Employment Rate

Unemployment rate is another important indicator of economic performance. However, it is heavily influenced by country-specific legislation and programs to combat joblessness. Moreover, whenever unemployment is too high and long-lasting, workers might quit the labor market, making intercountry comparisons particularly unreliable.

A more direct indicator could be the probability of being employed at working age. The employment rate in the population aged 15–64 years is often used. This basic indicator has already gained widespread acceptance in labor economics and statistics.

While such an indicator admittedly does not tell us anything about job quality or whether jobs match people’s expectations, it nevertheless means a lot when looking for a job or being exhausted by long periods of job search. It is also a sustainability indicator as it is an important parameter for the long-term future of retirement plans and public finances.

All Statistics Are Limited

It is important to note that all statistics have some limitation.

Real GDP will always be useful for showing the stage in the economic cycle. It is of some use in indicating living standards. But, it is far from the ultimate guide. Even employment rates can be partially misleading. For example, is the employment temporary or permanent? Employment figures have been better than expected, but there has been a rapid rise in labor market insecurity as well.

Therefore, there is always a need to look at several statistics at the same time, and, overall, it is important for economists to look beyond the headline statistics to give a better overall picture of economic welfare.

Measuring Microeconomic Performance

Microeconomic performance signals a firm's success in areas related to its assets, liabilities, and overall market strengths. To know how well a firm is performing, economists employ some economic indicators that directly or indirectly enable economists to judge whether economic performance has improved or deteriorated. These indicators usually include:

1. Efficiency and productivity
2. Long-term growth

Efficiency indicates that production proceeds at the lowest possible per-unit cost. Productivity is an average measure of the efficiency of production. It can be expressed as the ratio of output to inputs used in the production process, i.e., output per unit of input.

Note that productivity growth, in particular, is seen as the key economic indicator of innovation and it is a crucial factor in production performance of both firms and nations. Increasing national productivity can raise living standards because more real income improves people's ability to purchase goods and services, enjoy leisure, improve housing and education, and contribute to social and environmental programs. Productivity growth also helps businesses to be more profitable.

Firms' performance, particularly measured by efficiency and productivity, is a long-standing topic in economic studies (Coelli et al. 2004; OECD 2001).

Research developments in this direction are mostly related to methodological advancement. The empirical literature on firm efficiency has been dominated by a nonparametric approach – the data envelopment analysis (DEA) (Charnes et al. 1994; Seiford 1996). The main advantages of DEA compared to the standard econometric

technique are that: (1) it does not require any form of functional specification; (2) it is able to handle multiple inputs and outputs readily in any (in)efficiency theoretical paradigm. Based on the input and output data from DEA, a Malmquist Index can be constructed to measure productivity change. The criticism of the DEA method is related to its potential statistical shortcomings. A further development of this method is to use the bootstrap approach to obtain statistical properties.

Another well-developed method is the stochastic frontier approach (a parametric approach) (Aigner et al. 1977). Its principal advantage lies in the decomposition of deviations from the efficiency levels between noise (stochastic error) and pure efficiency; however, it faces the challenge of determining the appropriate functional forms. Recently, a semi-parametric method which combines nonparametric and parametric approaches has been applied (Bernini et al. 2004).

In addition to efficiency and productivity, firms' long-term growth – that is, sales, turnover, or profit growth – is also used to measure firm performance. Based on the production function (i.e., input–output), significant input factors are identified to explain the growth. This line of research departs from the SCP paradigm but does not seek explanations of firm growth from market structure or conduct.

Definition

Economics imperialism is a type of an interdisciplinary relation between the scientific discipline of economics and other disciplines of the social sciences. The disciplines that are often claimed to be “imperialized” by economics are sociology (see Granovetter and Swedberg 2001; Swedberg 1990), political science (see Hodgson 1994; Sigelman and Goldfarb 2012; Kuorikoski and Lehtinen 2010), anthropology (see Marchionatti and Cedrini 2016), geography (see Mäki and Marchionni 2010), and law (see Medema 2018; Davies 2010; Fink 2003). Hence, the law and economics movement is seen by some as one of the manifestations of the imperialism of economics in the social sciences (in this case – in legal scholarship). Below, I review the general debate on economics imperialism, and then I discuss the attempts to analyze law and economics as a case of economics imperialism.

Introduction

Recently, in the philosophy of science literature there is a discussion on scientific imperialism, of which economics imperialism is just an instance. This debate has revolved around the question of the permissibility of the application of scientific theories and methods outside the discipline in which they were initially introduced. Philosophers of science have attempted to clarify what it means for a theory or a discipline to be applied outside its own field or domain, and whether such an application can be understood as imperialistic (Dupré 1994, 2001; Mäki 2013; Clarke and Walsh 2009; Kidd 2013; Clarke and Walsh 2013; contributions to the volume edited by Mäki et al. 2018). It is debated whether scientific imperialism is a neutral or

normatively loaded term, how to establish criteria for assessment of imperialistic practices in science, how to categorize different instances of scientific imperialism, as well as whether the political metaphor of imperialism is useful at all in order to account for relationships between scientific disciplines. Mäki et al. (2018) argue that scientific imperialism challenges two central tenets of current scientific practice, as it calls into question two widely spread ideas: (1) that the broader the scope of a scientific theory, the better; (2) that interdisciplinary exchanges bring indisputable benefits (p. 1).

The term “economics imperialism” has been used in the pejorative sense by the critics of the idea of applying economics outside its domain (Fine and Milonakis 2009; Davis 2015; Hodgson 1994; Nik-Khah and Van Horn 2012) and in the approbatory sense by some economists (most notably by Becker 1971; Hirshleifer 1985; Stigler 1984; Lazear 2000; Radnitzky and Bernholz 1987; Tullock 1972) who have advocated the idea of expanding economic theories and methods to the topics studied by the less advanced, in their opinion, social sciences. “Economics imperialists” have argued that such an expansion is justified by economics’ “growing abstractness” and “generality” that economics achieves thanks to “the machine of maximizing behavior” (Stigler 1984); by the universal applicability of economics’ analytical categories (Hirshleifer 1985); and by economics’ intellectual rigor (Lazear 2000; Posner 1989). Moreover, Mäki (2009) emphasizes that the expansion of economics has been often justified in terms of the ideal of unification – economics is supposed to provide, in the opinion of “imperialists,” a unifying theory for the social sciences. Fine and Milonakis (2009) claim that the theoretical development in economics that made the expansion of economics possible was the marginalist revolution and its basic concepts of equilibrium (see: ► “[Equilibrium Theory](#)”), rationality (see: ► “[Rationality](#)”), scarcity – “universal in content and application” (p. 8).

Criticism of Economics Imperialism

However, critics of economics imperialism, apart from questioning the alleged advancement of

economics as a social science, often point out the importance of non-epistemic arguments and non-academic standing of economics for the successes of its imperialistic scientific practices. For instance, Nik-Khah and Van Horn (2012) claim that economics imperialists of the Chicago School wanted in the first place to influence policy approach by proposing their view on what constitutes the economic analysis of state policy. “Stigler’s program to study ‘governmental control’ constituted a new and distinct approach, rather than mere application of a core Chicago approach to a new domain” (p. 217). Amadae (2018) stresses the importance of politically motivated expansion of the rational choice theory – its attractiveness for nuclear deterrence made it prestigious in nonacademic contexts and in this way has strengthened its standing within academia as well. In this context the affinities of the Chicago School analysis with neoliberalism are often emphasized. Nik-Khah and Van Horn (2012) claim that economics imperialism cannot be really understood if one does not take into account the Chicago School economists’ involvement into the revival of the liberal project, known as neoliberalism – redefinition of the social and the political sphere through the concepts of neoclassical economics – and its impact on the real-world policy design. Therefore, partly in response to this “performative” aims of the Chicago School (Davis 2015), or “pedagogical” effects of the rational choice theory (Amadae 2018), some critics of economics imperialism have argued that the conceptualization of social relationships through the categories of neoclassical economics, or of rational choice, is inherently inadequate (Fine and Milonakis 2009) and can lead to ethically objectionable large-scale sociocultural consequences (Marino 2018) by influencing agents’ self-understanding (Clarke and Walsh 2009).

Is All Economics Imperialistic?

It should be noticed, however, that upon inspection we find out that economics imperialism, as each instance of scientific imperialism, is in fact a relationship between smaller epistemic units than scientific disciplines (Davis 2015; Małecka and

Lepenies 2018; Chassonnery-Zaïgouche 2018). The analysis of cases of economics imperialism makes it clear that it is never the case that the *whole* discipline of economics is “imperializing,” e.g., the *whole* sociology. Thus, as Davis (2012) argues, “economics is not all economics” (p. 210). It is usually a particular research program that develops within the discipline of economics and which is being transferred outside, as well as within, economics’ institutional borders.

In contemporary discussions, it is often claimed that only neoclassical economics, and more specifically the Chicago School and its price theory, are extended to other domains and scientific fields (Davis 2015; Nik-Khah and Van Horn 2012). However, Amadae (2018) argues that it is in fact not the neoclassical economics with its formalization of diminishing marginal utility, what constitutes economics imperialism, but rather the game theory with its view on agency as strategic competition between actors who satisfy their preferences. Guilhot and Marciano (2018) complicate the picture by showing that what is now called the economics imperialism in political science was the application of the rational choice theory to the questions of the political decision-making: it was possible rather due to the rising importance of the decision theory across the social and behavioral sciences after the Second World War. Furthermore, few researchers emphasize that some of the economic approaches, or research programs that we consider imperialistic today, were in fact quite marginal within economics, back in the days. Becker’s (see ► “Becker, Gary S.”) application of rational choice and price theory to the analysis of social phenomena is one of the examples (Chassonnery-Zaïgouche 2018; Vromen 2009). Chassonnery-Zaïgouche (2018) analyzes economic studies of discrimination and claims that Becker influenced, imperialized, with his work mainly the discipline of economics and has had, in fact, marginal impact on other social sciences studying discrimination.

Despite the seemingly intuitive appeal of the term “economics imperialism,” it is not clear what does it mean that one research program is imperializing another, or other. Economics imperialism has been defined, for instance, as

“colonisation of the subject matter of other social sciences by economics” (Fine and Milonakis 2009), as “a form of economics expansionism where the new types of explanandum phenomena are located in territories that are occupied by disciplines other than economics” (Mäki 2009), or as “the attempt to extend the core ideas of neoclassical economics to cover social science as a whole” (Hodgson 1994). Most of the definitions account for the metaphorical use of the notion of imperialism as we know it in political context. There is a discussion, however, to what extent the metaphor of imperialism should be taken seriously when talking about scientific practices. The notion of imperialism is normatively loaded and most scholars believe that one cannot ignore this normative dimension in the case of economics imperialism (Mäki 2013, who defines scientific, and economics, imperialism neutrally, is an exception here). Małecka and Lepenies (2018) provide the definition of scientific imperialism, that applies to economics imperialism, in which they account for the widely shared belief that there is something normatively problematic about economics imperialism. They stress the importance of epistemic and non-epistemic factors for being able to define and identify economics imperialism. Scientific imperialism is an activity that is related both to a certain view on the progressive character of a novel application of an existing research approach (the epistemic aspect) and to a power to favor this approach at the expense of other approaches in terms of academic and non-academic prestige, or/and resources (the institutional aspect).

Law and Economics as an Instance of Economics Imperialism

Law and economics is often seen as a result of the expansion of the Chicago School approach to law (Mercuro and Medema 2006; Medema 2015, 2018). Sometimes it is understood, more broadly, as an application of orthodox, or neoclassical economics (Jackson 1984; Davies 2010), or of game theory (Pearson 1997) to law. Mercuro and Medema (2006) even argue that law and economics

“has been the most successful of economists’ imperialistic forays into other disciplines” (p. 100).

The application of the price theory to the analysis of law is grounded on the premise that individuals are rational maximizers of their utility, that they respond to price incentives also in non-economic settings and that law can be treated as an incentive. Medema (2015) stresses the importance of Gary Becker’s (see ► “Becker, Gary S.”) works that advanced the analysis of all social phenomena with the tools of price theory (and econometrics) for the development of economic analysis of law. Medema (2015) differentiates this “new” law and economics, inspired by the work of Becker, as well as of Richard Posner (see ► “Posner, Richard”), from the “old” one, initiated by Aaron Director (see ► “Director, Aaron”), whose aim was to simply analyze the impact of legal rules on economic performance. According to Medema only the “new” law and economics has features of scientific (economics) imperialism (compare also Epstein 1997 on periodization of law and economics and Harnay and Marciano (2009) on the difference between law and economics and economic analysis on law).

Posner (1989) justifies the application of neo-classical economics to law by the rigor that this type of economic analysis allegedly offers, as well as by the possibility of funding the truly “scientific” analysis of law in this way. Cooter (1981) points out that the reason for the economics imperialism in law is the “discovery” by economists a niche in legal scholarship – a lack of quantitative reasoning. Cooter (1995) also emphasizes the importance of an attempt for unification for applying economics to law.

The historical case study made by Medema (2018) on the ad hoc Joint Committee of the American Economic Association and the Association of American Law Schools established in 1966 to explore the prospects for interactions between lawyers and economists challenges the commonly spread narrative about neoclassical economists conquering a new field. The study demonstrates that lawyers played a crucial role at the early stage of bringing economics to their studies and in replacing “the traditional methods of legal analysis” (Medema 2018, p. 110). However, later on

the application of neoclassical economics to law had been opposed by some lawyers as being too abstract an analysis, untested, irrelevant to the courtroom (Cooter 1981). Law and economics as a scientific project of explaining legal phenomena has been also scrutinized and criticized. For instance, Jackson (1984) criticized law and economics' scientism and its technocratic attitude that made it so dominant in the legal scholarship. For other critics law and economics is mainly a manifestation of "the neo-liberal project of applying neo-classical economics to state sovereignty" (Davies 2010, p. 64) that has been advanced by non-epistemic arguments and normative views on policy as complying with the goals of economic efficiency (Davies 2010; Fink 2003).

Ecosystem Services

Sébastien Roussel

Department of Economics, CEE-M, Université Montpellier, CNRS, INRA, SupAgro, Université Paul Valéry Montpellier 3, Montpellier, France

Definition

Ecosystem services are services provided by the ecosystems and contributing to human well-being. These services play a crucial role in signaling the reliance of societies with regards to ecological systems and functions, as well as

biodiversity. Disservices stand for the opposite of ecosystem services.

Introduction

Ecosystem services correspond to a modern way to figure out the role of the environment for human society, in particular in economics through the valuation of ecosystem goods and services (Gómez-Baggethun et al. 2010; Braat 2016). These services have been promoted by increasing and complementary contributions both by policymakers and academic researchers towards their agenda to promote sustainable development, especially regarding the environmental issues at stake.

Over the past decades, landmark international initiatives to assess their social value range from the Millenium Ecosystem Assessment (MEA) (2005) and The Economics of Ecosystems and Biodiversity (TEEB) (2010) to the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) (Pascual et al. 2017). In addition, international initiatives to set a policy agenda include among others initiatives by countries or group of countries (e.g., the US White House to include ES in Federal Policy (October 7, 2015) or the future EU Biodiversity strategy 2020), or initiatives by international bodies (e.g., the UN-REDD program to design and support Reducing Emissions from Deforestation and Forest Degradation + (REDD+) actions to cope with deforestation).

In terms of the history of economic thought, Mooney and Ehrlich (1997) date the modern history of the benefits got by human people from the ecosystems from the publication of Georges Perkins Marsh's book entitled *Man and Nature* in 1864. The concept of ecosystem service appeared effectively in the late 1970s (Ehrlich and Ehrlich 1981; Ehrlich and Mooney 1983), and the word service has been since used to reveal the benefits from ecological systems and functions in a utilitarianism framework, in order to highlight their social significance. According to Gómez-Baggethun et al. (2010), the role of Nature and then ecosystem services for human society depends on the considered economic perspective.

Firstly, Nature’s benefits switch from solely use values in classical economics to exchange values in neoclassical economics. Secondly and more recently, in the environmental and resource economics literature, Nature’s benefits are monetizable and exchangeable services, while in the ecological economics literature, there are controversies on monetization and commodification of Nature’s benefits. More precisely, the latter distinction depends on the status granted to the natural capital and the extent of the literature at stake, from the inclusion of market failures to social ecological economics.

Ecosystem Service Classification and Valuation

Many ecosystem service classifications have emerged over the past three decades with regards to the contribution of different types of

ecosystems to human well-being (MEA 2005; TEEB 2010). Following the revision of the System of Environmental-Economic Accounting (SEEA) under the umbrella of the United-Nations (UN), the Common International Classification of Ecosystem Services (CICES) was then developed to provide a hierarchically consistent and science-based classification (hosted by the European Environment Agency (EEA)).

Classifications of ecosystem services traditionally start from so-called supporting services that literally support other services mainly divided in provisioning services, regulating services and even maintenance services, and information services. Those services then contribute to well-being in providing security, basic material for good life, health, and social relations, and to a larger extent have public good characteristics. Figure 1 sums up these relationships in showing how ecosystem services and human well-being are linked from MEA (2005). We may underline that the status of

Ecosystem Services, Fig. 1 Relationships between ecosystem services and human well-being (from MEA (2005))

biodiversity remains debated among scholars as this can either be a support service through habitats for species or a single service as a whole. Moreover, relatively new contributions in the literature stress that multiple services are generated at the same time and consequently that this is suitable to use rather the concept of bundle of ecosystem services (Raudsepp-Hearne et al. 2010; de Groot et al. 2012).

Once classified and described with regards to an according typology, ecosystem services have to be valued to assess their contribution to society. Seminal papers in the literature range from methodological papers (de Groot et al. 2002) to effective value assessment even towards global values (Costanza et al. 1997, 2014; de Groot et al. 2012). Values are traditionally separated into ecological value, socio-cultural value, and economic value (de Groot et al.

2002). The economic value is then linked to use and non-use values and is measured in using economic valuation techniques either through direct market or indirect market/nonmarket valuation – avoided cost, replacement cost, travel cost, hedonic pricing, contingent valuation, and more recently choice experiment valuation – to derive willingness to pay (WTP) or willingness to accept (WTA) for the availability of these services.

Recent contributions highlight also the spatial dimension of ecosystem services and how this impacts their value (de Groot et al. 2012; Tardieu et al. 2015), either at the local scale or at the global scale through land use scenarios (Gascoigne et al. 2011). Consequently, the number, the location, and the characteristics of the beneficiaries may generate distance decays (Bateman et al. 2006; Tardieu et al. 2013). Figure 2 illustrates the spatial

Ecosystem Services, Fig. 2 Spatial dimension of ecosystem services: relationship between supply, demand and values (from Tardieu et al. (2013))

dimension of ecosystem services and therefore the overall relationship between supply, demand, and values (Tardieu et al. 2013) adapted from Haines-Young and Potschin (2010).

Environmental Law, Rules, and Incentives

Following the assessment of the significance of ecosystem services and their contribution to social welfare, the step forward consists in their inclusion in decision-making (Daily et al. 2009). Until the early 2000s, ecosystem services were indeed poorly included in cost-benefit analyses. The goal is then to integrate ecosystem services in landscape planning (de Groot et al. 2010) and more precisely strategic environmental planning and assessment (Kumar et al. 2013; Tardieu et al. 2015), to ensure the protection of the ecosystems. To this aim, environmental law can play a crucial role in allowing economic information to be used in decision-making.

According to Salzman (1998), environmental law can help for a better understanding of ecosystem services provision and then to assess their value by the creation of information markets. Indeed, the contribution of the economic analysis can take place only through a legal framework of rules and incentives. For example, the clean water acts regulation, the Code of Federal Regulations or the National Oceanic and Atmospheric Administration (NOAA) in the USA have created over the years information markets to gather data, to provide environmental impact statements, and to allow damages valuation on wetlands (Salzman et al. 2001). Moreover, the European Commission is currently preparing a Directive on the No Net Loss (NNL) of biodiversity and ecosystem services that can help to reach this aim (Wende et al. 2018).

Regarding the rules and incentives in environmental law, one could consider the following principles according to Salzman's "Five P's" (2005, 2013). These principles are respectively prescription, (financial) penalty, persuasion, property (rights), and payment. To sum up, prescription refers to the legal framework

ranging from the command-and-control regulation to the expressive function of law with regards to social norms. Financial penalties alter behaviors through financial signals (e.g., a tax mechanism). Persuasion refers to information instruments towards stakeholders regarding suitable management practices and behaviors. Property rights embody the allocation of private rights or (transferable) use rights. Finally, payment often refers to positive monetary incentives (e.g., a subsidy mechanism). These principles are complementary and are applied differently according to the ecosystems and the services at stake.

Considering the property rights and the payment principles, this contributes to the creation of market-based instruments to protect ecosystem services (Salzman 2005; Miteva et al. 2012) and to a larger extent to the implementation of payments for ecosystem services (PES) (Alix-Garcia and Wolff 2014). PES reward the landholders either to enhance their activities in favoring the provision of ecosystem services or to cover their opportunity costs in giving up their activities if these are harmful for the ecosystem services in question. PES are increasingly used in the forestry sector regarding water purification and supply or carbon storage for example (Delacote et al. 2016). Note that there is currently an increasing literature to assess the successes and failures of PES systems.

Last, brand new mechanisms to protect ecosystem services are biodiversity offsets that take place under legal constraints. Biodiversity offsets are activities that provide measurable and additional ecological gains that are equivalent to the ecological losses in an impacted area. Biodiversity offsets operate even as a market of "mitigation credits" under the control of regulators if we take the example of wetland mitigation banking in the USA (Vaissière and Levrel 2015). In this case, exchanges between gains and losses are implemented to achieve no net loss of wetland and services protection, under the supervision of the United States Army Corps of Engineers (USACE) and the United States Environmental Protection Agency (USEPA).

Efficiency

Fatih Deyneli

University, Denizli, Turkey

“An effective judiciary is predictable, resolves cases in a reasonable time frame, and is accessible to the public.”

Marina Dakolias 1999 Court Performance around the World: A Comparative Perspective

Definitions of Efficiency in Economics and in Law

The economic analysis of law relies upon micro-economic principles. Efficiency, a significant concept within microeconomic theory, is one of the key concepts in the economic analysis of law. There are different types of efficiency in economic literature. These types are defined as follows.

Productive Efficiency: The very first answer to the question “what is efficiency?” may be the ratio of the work done or output obtained by a certain amount of input. This is a state of maximum output using a certain source and technology during production. In other words, we can accomplish maximum output with the available source and technology we have. If the production with the sources and technology at hand is lower than maximum output, the state of inefficiency comes into picture (Arnold 2011).

Pareto Efficiency: Created by nineteenth century economist and sociologist Vilfredo Pareto (1848–1923), this term is a beneficial criterion in comparing the output from different economic institutions. If resources can be allocated evenly in which it is impossible to make any one individual better off without making at least one individual worse off, a Pareto improvement can be obtained. If allocation leads the way to Pareto improvement, this situation is called Pareto inefficient. In this situation, economy cannot have all that it could obtain from its resources. If we cannot find a way to make any one individual better

off without making at least one individual worse off, this situation is called Pareto efficient. In this situation, economy can have all it could obtain from its resources (Varian 2010; Besanko and Braeutigam 2011).

Kaldor-Hicks Efficiency: The application of Pareto efficiency concept to justice leads to a real problem. Firstly, there is one winner and one loser in justice, which originates from the compulsory characteristic of justice (Dimock 2005). Secondly, Pareto efficiency is also applicable to free market rules. Justice services, necessary for the implementation of law, are public commodities. Therefore, Pareto efficiency needs transformation before being used in the economic analysis of law.

Kaldor and Hicks transformed Pareto efficiency so that it can be added to the area of law which has a compulsory characteristic. Kaldor-Hicks efficiency criterion can be defined as: “a change is an improvement by Kaldor-Hicks criterion if the gainer value their gains more highly than the losers their losses” (Mathis 2009). This is basically a cost-benefit analysis. In cost-benefit analysis, when benefit exceeds cost, the project is commenced so it implies that winners may regulate losers (Cooter and Ulen 2011).

Justice System Efficiency

According to Posner, justice system has two expenditures, which are fault expenditure and direct expenditure. Fault expenditure is the failure of justice system in the distribution and other social functions. Direct expenditure is the cost of time, stationery, phone, and office work spent by judges, lawyers, and others. Posner states that fault expenditures are as real as direct ones and the economic aim should be to lower these two expenditures. The aim of justice system should be to lower both fault and direct expenditures (Posner 1973).

European Commission for the Efficiency of Justice defines justice system as a system composed of input, production, and output. These inputs, productions, and outputs within this system are summarized in Table 1 (Albers 2003). The demand side of justice system involves the

Efficiency, Table 1 Input, production, and output of justice system according to CEPEJ

Input	Production	Output
Number of courts	Average time of criminal cases	Number of resolved criminal cases
Court budget		
Information budget of courts	Average time of commercial cases	Number of resolved commercial cases
Numbers of professional judges		
Numbers of members of the jury	Average time of divorce cases	Number of resolved divorce cases
Numbers of deputy judges		
Numbers of justice staff	Average time of social security cases	Number of resolved social security cases
Numbers of other staff		
Average judge salary	Average time of immigrant cases	Number of resolved immigrant cases
Average justice staff salary		
Number of criminal cases	Average time of fiscal cases	Number of resolved fiscal cases
Number of commercial cases

processing of incentives and constraints in lawyers' and parties' behavior (Rosales-Lopez 2008). The supply side of justice system involves factors such as the budget; number of judges, prosecutors, and assistant staff and their working time; and technology (Buscaglia and Ulen 1997).

The demand side of justice system and fault expenditure is mostly related to Kaldor-Hicks efficiency concept, while the supply side of justice system and direct expenditures is mostly related to the concept of productive efficiency.

Common Efficiency Indicators

Economic analyses have also begun to be used in the economic analysis of law. Quantitative measurements such as numbers of incoming cases, disrupted cases, and resolved cases and numbers of crime and accident have also gained importance in these analyses (Posner 2006). Due to different judicial systems in different countries, there are some differences among indicators. Despite these differences, common indicators about the efficiency, quality, and performance of justice services in international level have been used as reference point in many studies (Dakolias 1999). Developed for the measurement of justice system efficiency, these indicators benefit in objectifying the concept of justice. By this way, the concept of justice becomes appropriate for economic and econometric analyses.

The most commonly used one of these indicators is clearance rate. International institutions make use of other indicators to analyze the efficiency of justice services. Table 2 provides the websites of

Efficiency, Table 2 International institutions working on the efficiency of justice system

Name of institution	Web page
OECD	http://www.oecd.org
World Bank	http://www.worldbank.org/
European Commission	http://ec.europa.eu/justice/

international institutions for more indicators and analysis of these indicators on country basis.

Clearance rate is calculated by dividing the number of crimes that are “cleared” (a charge being laid) by the total number of crimes recorded. It may also be defined as the response of justice system to the clearance rate and demand in justice system – applications to the justice system. If clearance rate is more than 100%, courts begin to deal with the cases remained from the previous year. If clearance rate is less than 100%, there will be cases unresolved (Dakolias 1999). Clearance rate is measured as follows (CEPEJ 2012):

$$\text{Clearance rate} = \frac{\text{Resolved cases in a period}}{\text{Incoming cases in a period}} \times 100$$

Efficiency, Types of

Henk J. ter Bogt

University of Groningen, Groningen, The Netherlands

Abstract

Efficiency is an important concept in the field of law and economics. The precise meaning of the term efficiency is not unequivocal and depends on the context in which it is used. In practice, efficiency often relates to economic efficiency. However, such forms as social and political efficiency can also be very important for the continuity of a society or an organization.

Efficiency types in organizations and society: Different kinds of measures which all indicate the optimal use of specific material or immaterial scarce resources in organizations and society.

Introduction

Efficiency is a well-known word in everyday language. It is also a core concept in the law and economics literature, a field which deals with the economic effects of legal rules and constraints and the way in which these rules and constraints can contribute to “efficiency.” To put it in more general terms, it could be claimed that the traditional emphasis of the law and economics literature has been on finding efficient legal rules and structures, i.e., instruments which promote economic efficiency. This objective implies finding an optimal allocation of the resources available and realizing a maximum quantity of outputs via these means. Laws and rules can play a role here (Coase 1960; Calabresi 1961). In principle people are supposed to act rational in the law and economics literature, which implies that based on their economic rationality, they strive for economic efficiency. In later additions to the law and economics literature, however, efficiency is used in broader terms,

referring to more aspects than only economic efficiency.

The specific focus on “efficiency” might suggest that the precise meaning of the concept is always clear. However, in economics different types of efficiency can be distinguished. And in later elaborations of the law and the economics literature, even more types have been added, such as social efficiency and political efficiency, each with their own specific definitions. All of these definitions may refer to “maximizing” something, i.e., an output, by using a minimum amount of “inputs.” What has to be maximized, and what the inputs and outputs are, varies and relates to the specific angle and subject area chosen. This optimization could relate, for example, to economic welfare, but also to public benefit (which can include immaterial and nonmonetary elements). Furthermore, in the later additions to the law and economics literature, human behavior has received increasing attention (see, e.g., Jolls et al. 1998; Korobkin and Ulen 2000). This has been done, for example, via concepts such as bounded rationality (people may want to choose the best alternative available to them, but they can only acquire full knowledge of a limited number of alternatives) and bounded self-interest (although people may be focussed on their own interests and utility, this does not necessarily imply that they maximize utility without caring about others). Despite these refinements, however, in practice the ultimate focus of much of the law and economics literature still seems to be on the realization of optimal economic efficiency.

Below, first, the basic concepts of inputs and outputs will be introduced, followed by a discussion of the more traditional economic efficiency concept and the elements in which it can be subdivided. Next, some other types of efficiency will be discussed briefly and a conclusion will be presented.

Inputs and Outputs

Some of the concepts mentioned above require some further explanation, because they are the basic components in the analysis of efficiency.

The various forms of efficiency all deal with inputs and outputs. In a production process, examples of the *inputs* required to produce a certain output, i.e., a good or a service, are direct and indirect labor hours, capital, materials, machine hours, ICT, housing, knowledge, and transport. These inputs can also be called resources. Together, the inputs are the costs made in the production of the outputs. The *outputs* are the “products” produced, for example, the goods and services, which are the result of a production process in an organization. So the production process transforms the inputs into outputs (which may lead to certain effects, i.e., outcomes considered desirable by an individual or society, resulting, e.g., in utility maximization). In order to be able to measure and compare the different inputs, they generally have to be expressed in monetary values.

Economic Efficiency and Its Dimensions

The term efficiency as commonly used generally refers to the ratio between the inputs employed and the outputs realized. More precisely, it refers to the maximization of output produced by a unit of input. If more output can be produced per unit of input, the efficiency increases. Linking outputs to inputs in this way could also be called measuring the productivity. Depending on how much output is produced by a unit of input, the common term “efficiency” can also indicate organizations as being less or more efficient. Therefore, the general criterion based on which different organizations are compared is their “efficiency.” However, in the academic economic and law and economics literature, many authors define “efficient” in more specific and absolute terms.

When the term efficiency is used in the field of law and economics, it generally refers to the so-called economic efficiency, which can be subdivided into two types: productive or technical efficiency and allocative efficiency. These categories together form the overall economic efficiency (Coelli et al. 1998, pp. 3–5).

In an economic context, the first type – productive or technical efficiency – is defined as

follows: “efficiency is the difference between the actual input/output ratio and the ideal ratio” (Jackson 2011, p. 16), all other things – such as the production technology and the quality of the output – remaining equal. So the ideal ratio is considered to be the result of the optimal possible use of a certain quantity of input, and in that situation the input yields the maximum quantity of output attainable on the basis of this input (i.e., the “production frontier,” as it is labeled by economists, has been reached). In economics, this type of efficiency is called *productive* or *technical efficiency* (terms which can be considered as synonyms). Productive (or technical) efficiency relates to an organization’s production costs. It is achieved when the organization’s outputs are produced at minimum average costs (i.e., only if this point of minimum average costs is achieved can one speak of an organization being “efficient”).

Although organizations and/or society can be productively efficient, this does not automatically imply that the products produced are valued by the citizens/consumers. The other dimension of economic efficiency, called the *allocative efficiency*, therefore addresses the question whether the “right products” are produced. If a company would produce steam engines in a productively efficient way whereas nobody needed these items, a major problem could arise concerning using the resources for this production process. Allocative efficiency indicates whether the resources in society are allocated in an optimal way, given a particular behavioral assumption, for example, utility maximization (but the behavioral assumption could also be, e.g., profit maximization or cost minimization). This means that allocative efficiency concentrates on whether a society’s resources (inputs) are allocated to those domains of activity and output which bring the citizens/consumers the maximum utility (where in this context utility is supposed to be related to the availability of economic goods). Expressed in more technical economic terminology, allocative efficiency refers to a situation where the price which consumers are willing to pay for a product (this price indicates the utility or value attached to the product) is equal to the cost of the resources used for realizing this product (i.e., the marginal

cost of the product). In an alternative definition allocative efficiency indicates the situation in society in which the available resources (inputs) are used in such a way that it would not be possible to increase one person’s utility without decreasing that of another. In economics, the latter example is also called a Pareto-efficient or Pareto-optimal allocation.

A concept related to the productive or technical efficiency category is the so-called *X-efficiency*. Being X-efficient means that an organization employs its internal resources in an optimal manner, i.e., in such a way that the average costs are reduced to a minimum. However, if the competition in the market is imperfect, for example, because of a monopoly, a situation of X-inefficiency may exist, also on a longer-term basis (Leibenstein 1966). Here the organization is not capable of achieving productive or technical efficiency and produces its outputs at higher costs per unit than technically considered necessary.

The above depicts the most frequently used and most important dimensions of economic efficiency. However, apart from the strictly economic forms of rationality, there are also other variants relevant in practice, which are not necessarily of a higher or lower order. Next, an outline is given of two of them.

Social Efficiency

Although social efficiency relates to an assessment of the welfare in a society in a mainly economic sense, it has more recently also been used in connection with all kinds of noneconomic topics (e.g., social, political, and cultural) which can play a role in and influence the public benefits. When used in this broader context, social efficiency refers to the maximization of certain “outputs” in society (e.g., the contribution to an objective such as sustainability or social justice) via the inputs available (see, e.g., Lefebvre and Vietorisz 2007).

The more traditional use of the term social efficiency, however, goes back to Coase (1960). In that context *social efficiency* indicates the maximization of the social welfare, which means

a maximization of the revenues obtained. This maximization of revenues suggests an economic focus. The revenues are considered to be maximized if the inputs and outputs are used in such a way that the social cost of production is equal to the social benefit (or, in more technical economic terminology, if the social marginal benefit of the consumption of the output is equal to the social marginal cost). If expressed in this way, social efficiency seems to be closely linked to allocative efficiency. However, the concept of social efficiency includes paying attention to the existence of the so-called externalities (and markets which are not perfectly competitive). When focussing on welfare at the level of society, the effect of production on different individuals or groups is considered with the aim to maximize the social welfare, i.e., attaining social efficiency.

As social efficiency and “externalities” are important in much of the law and the economics literature, they are dealt with in some more detail. External effects relate to the influence of the activity or action of an individual or organization on other individuals or organizations. Such an influence could be, for example, the pollution caused by the activities of a factory in the gardens of the people living in the vicinity. This effect, an externality, should be taken into consideration when social welfare has to be determined. In the case of the factory, elements should be taken into account like the negative effect of the production activities on the living environment of the people in the surrounding area and the value of their property. In principle, the factory could negotiate about a compensation for such negative effects with each individual neighbor. However, if the factory would have to negotiate with all its neighbors individually, its “transaction costs” may rise to an unacceptable level (in this case the transaction costs could include, e.g., the costs involved in searching for alternatives to avoid or compensate the pollution, negotiations, and the monitoring of the agreements made). Here certain legal rules which prescribe how to act in the case of an externality (and what kind of negative effects has to be accepted by one or both of the parties) could be helpful in reducing the cost of making contractual arrangements (and in reducing

transaction costs) and approaching an optimal economic result for society (Coase 1960; Calabresi 1961).

Although social efficiency as developed on the basis of the ideas of Coase and Calabresi mostly refers to economic welfare, Coase (1960, p. 43) suggested that the analysis “of different social arrangements for the solution of economic problems should be carried out in broader terms than” only the economic context (i.e., it should be broader than only the “comparison of production values as measured by the market”). If such a broader interpretation of the concept of efficiency is adopted, it seems to be very similar to the abovementioned maximization of social benefits.

Political Efficiency

In a political environment, the goal function, i.e., *ter what has to be maximized* (the “outputs”), may differ from that in a “strictly economic” context, which also applies to the inputs concerned. This could particularly be the case when special interest groups try to influence political decision-making (Buchanan and Tullock 1974, pp. 284–287, 302–305). Since the law and economics literature considers both the effects of legal rules and the way in which they develop and are ultimately formulated – which is basically a political process – several authors have also included the political context in their work.

A politician who has to decide about the content of a law could be interested in its effects in terms of both economic and social efficiency. Taking economic and social efficiency into account can be important in avoiding dissatisfaction from within society. However, the politician may also be interested in the effect of the legal rules on his/her voters and the number of votes he/she and his/her party will receive in the next elections, i.e., political efficiency (Buchanan 1993; Gavious and Mizrahi 2002). From the perspective of political rationality, i.e., to survive as a political party or a politician, a rational approach would be to try to maximize the electoral support by using minimal “efforts.” *Political efficiency*

could then be expressed “as a ratio of the amount of ‘effort’ (including money and other production factors) made by politicians to the amount of electoral support gained by means of the politicians’ policies” (ter Bogt 2003, p. 180). The elements on which the politician’s efforts should focus can vary from case to case. This is because elements such as the public interest and social welfare are generally not that clearly defined in practice and can include many different components, which can also differ among citizens (who are the voters in elections). Furthermore, the political support of voters may not only depend on the economic efficiency of the government policy but also on other factors, for example, equal treatment, a focus on sustainability, and social justice (see also Wildavsky 1966, pp. 308–309).

To Conclude

In principle, depending on the specific context, the type of rationality may vary, and herewith the relevant type and definition of “efficiency.” Economic and law and economics literature were traditionally mainly focussed on economic rationality and efficiency. However, social efficiency and the related concept of social rationality have now also become important elements in the law and economics literature. Social efficiency as it is mostly used in practice is closely linked to economic welfare in society. But it can also include “noneconomic” elements, such as sustainability or social justice, and pertain to the broader level of public benefits. The idea of political rationality and political efficiency applies more specifically to political environments (although it seems that in practice “politics” can play a role in any organizational context). The political efficiency idea is partly related to Granovetter’s suggestion that in order to better understand economic activity and the organizational arrangements chosen, it is necessary to take both economic and social relations into consideration (Granovetter 1985, pp. 490–491).

In this way the law and economics literature and the concept of efficiency have gradually been

extended. The literature no longer only focusses on economic aspects but also includes behavioral elements, such as bounded rationality, as well as goals and outputs other than strictly economic ones. It now tries to include more elements from the “real world.” This approach leads to different types of efficiency, playing a role in different contexts. As might have become obvious from the examples given above, the operationalization and proper measurement of the various concepts and types of efficiency in empirical research can be problematic, even in the case of economic efficiency. However, this difficulty does not imply that it would be a futile exercise to consider – and if otherwise not possible only in qualitative terms – the effects of changes in rules and structures on a specific type of efficiency in an organization or in society.

Efficient Market

Michael Mitsopoulos¹ and Theodore Pelagidis²

¹Brookings Institution, Athens, Greece

²Brookings Institution, University of Piraeus, Piraeus, Attica, Greece

Introduction

In this article, we deal with some pieces of evidence that are needed to explain the paradox of rapid GDP growth in the face of the dismal competitiveness and inefficiency of the Greek economy during 1995–2008. We show how Greece's economy structural inefficiencies – inefficiency of justice included – have hit the domestic economy, and we present their impact on the current turmoil of the economy. We offer a specific explanation of the current unfortunate state of the economy, and we briefly summarize the reforms already undertaken towards efficiency. We also suggest avenues of necessary reforms to increase efficiency and overcome the current crisis.

The Engines of Growth, 1995–2008

In Greece, certain positive developments led to the strong growth performance observed since the mid-1990s and up to 2008. Figure 1 shows how Greece clearly outperformed, since 1995–1996, the benchmark eurozone economy. However, it is absolutely crucial to look at the factors of “growth” to see why, at least in the great part, this was superficial, fragile, and not based on the improvement, the deepening, or the expansion of domestic production.

These developments include, primarily, the proper liberalization of the credit markets at the

beginning of the 1990s, completed by the end of the 1990s. This was coupled with entry to the European Monetary Union. Combined these two developments lead simultaneously to macroeconomic stabilization and a steady increase of private credit after 2000. It has also to be stressed that the expansion of private credit replaced after the beginning of the 1990s the government deficit spending as the main way to finance the expansion of consumption in Greece, although data should be treated with caution. The most possible is that fiscal expansion reinforced private credit and private consumption expansion. As Fig. 2 shows by measuring demand injections to the GDP, the impact of these injections was important as a percentage of GDP for every year during a prolonged period that spans all the duration of Greece's strong performance.

The contribution of the stabilization of the macroeconomic outlook of Greece in the wake of EMU accession towards the expansion of private credit was significant, as is shown by the rapid fall of interbank rates after 1998 (Fig. 3), which reflect also the decline in the rates offered by commercial banks to households and businesses. (It also brought a significant fall of the inflation differential of Greece with respect to the eurozone average during the same period). It can be seen clearly how the expansion of credit to households fuelled the growth of private consumption during the past years (Fig. 4), and only just the period preceding the completion of the infrastructure projects that were prepared to be ready for the 2004 Olympic Games, private consumption kept accelerating in spite of a lull in the explosive growth of private sector credit.

But this exception is easily explained by the peak in the investment growth rate during that time (Fig. 5).

Besides the credit expansion, two other factors contributed significantly to Greece's growth performance during the 2000s. First is the shipping and tourism industry. These secure significant annual revenue inflows of about 25% of GDP that are added to the domestic demand and help to mitigate the huge trade balance deficit. Secondly, the fiscal stimulus given by the 2004 Olympic Games nourished through public borrowing

Efficient Market, Fig. 1 Real GDP (Source: AMECO)

Efficient Market, Fig. 2 Demand injections (Source: Bank of Greece, Ministry of Finance, European Commission Budget, and EUROSTAT)

Efficient Market, Fig. 3 Interbank rates

and that led to the improvement of certain key infrastructure facilities.

The rapid increase of new investment, both public and private (Fig. 6), also demonstrates the impact of the infrastructure investment that was largely financed by the EU structural funds. Still,

the rush into EU-financed infrastructure investment did not only contribute to investments and consequently to the creation of new jobs, as in the end many of these projects, when finished, actively boosted to some extent the productivity in the area surrounding Athens. The inflow of

Efficient Market, Fig. 4 % YoY change private consumption and Credit to households

Efficient Market, Fig. 5 % YoY change private consumption & investment. Greece. ESYE. Y2000 prices

funds from the European Union, within the context of the European Union structural funds and the Common Agricultural Policy, also contributed largely to the improvement of key productivity enhancing infrastructure facilities.

The Facets of Low Competitiveness and Inefficiency

However, at the same time, a wide range of factors persisted in contributing towards the poor

performance in certain other aspects of the Greek economy. The poor performance regarding competitiveness, to name just the most important one, is not only documented by numerous databases and surveys by international organizations and researchers but also by the persistent deficit of the current account in double-digit numbers (as a% of GDP), the persisting positive differential with the eurozone average inflation, and the unattractiveness of Greece to foreign direct investments that are practically zero (inflows minus outflows). Relatively recent research by

Efficient Market, Fig. 6 Investment as % of GDP

Efficient Market, Fig. 7 Inflation, HICP, goods & services. EUROSTAT

institutions like the OECD and the World Bank and a detailed presentation of numerous pieces of evidence indicate that the wide range of institutional weaknesses that prevail in Greece account, as a whole, for this dismal competitiveness performance.

The interesting part about the inflation differential of Greece with the eurozone (Fig. 7) is not that it is there, something that many would explain with the Balassa-Samuelson effect because of the rapid growth rate of the country. It is that it seems to emerge both in the goods (tradable sector) and services (non-tradable) subindexes, something that initially seems to refute the

Balassa-Samuelson argument (although to a certain extent, tourism that constitutes a significant part of services should be considered also as a “tradable service”).

An expository comparison with Ireland, where the inflation of goods is much lower than the inflation of services and that thus emerges as a textbook Balassa-Samuelson case, is most revealing.

The high inflation of Greece therefore seems to emerge as a result more of the demand increase, which is largely driven by the expansion of credit and the inflows from the EU structural funds as well as from tourism and shipping industry or

Efficient Market, Fig. 8 Services balance as % of GDP. Eurostat. Goods balance as % of GDP. Eurostat

public borrowing, which is not matched by a similar increase in the domestic supply of goods and services. And this is unlike the case of Ireland in which the surplus of the goods balance seems to finance a deficit in the services balance following again a pattern that fits well the standard predictions of the Balassa-Samuelson model.

The second piece of evidence that supports this argument is the excessive – and increasing – deficit of the goods trade balance, as a percentage of GDP (Fig. 8).

As a matter of fact, the deficit is of a magnitude that has never been seen in any country without the subsequent emergence of serious consequences. In the case of Greece, participation to the eurozone seems to have averted developments like the entrance into a spiral of high inflation and currency devaluations. As a result, the trade deficit in Greece can clearly demonstrate the existence

of a serious discrepancy between the growth of domestic demand and the increase of the domestic supply of both goods and services. It should be stressed that in the case of non-tradable services, the inflation differential is sufficient to document the discrepancy between supply and demand, but the emergence of such a differential for goods as well suggests the peculiarity of the case of Greece. Therefore, the evidence at hand would make it more appropriate to label Greece as a unique case of “quasi Balassa-Samuelson,” where exports are replaced by EU transfers and domestic credit expansion and the price level is pushed upwards both in the goods and in the services sector, which would actually be in line with the conclusions of recent research on the topic (Gibson 2007; Pelagidis and Toay 2007). The increase of the goods deficit follows as a natural consequence in this case, as increases in demand are satisfied by competitive and

available imported goods as there is no sufficient domestic supply of goods that can compete with the imports.

The third piece of evidence is the following: This persistent deterioration of the goods balance has been financed, besides from the surplus of the services account through foreign inflows in both Greek government bonds and into the stocks of Greek companies, at least until the present financial turmoil. However, it should be noted, rarely these inflows were FDIs. FDIs during the last 3 years were close to zero (\$0.9 bil. for 2006, \$2.5 bil. for 2007, and \$1.3 bil. for 2008, according to the Bank of Greece).

In fact, FDI inward flows for Greece as a percentage of GDP are very low for almost all years, something that is in line with the link between the attractiveness of the business environment and FDI (as described by authors such as Hajkova et al. 2007).

The performance of the goods balance together with the inflation differential with the eurozone for tradable goods suggests also that the cost of importing and distributing these competitive imported goods is higher compared to the eurozone. Furthermore, it suggests that the imports remain competitive in the domestic market in spite of this high cost of importing and distributing, which seems to be really damning for the competitiveness of the domestic supply of goods.

In spite of the mitigating effect of the surplus of the services balance, which is mainly driven by the performance of the shipping industry and tourism, the current account balance has remained for many years at a level (15% to GDP) that in any other country would have been associated with serious consequences. For the two sectors that contribute to the services account surplus, it should be noted that they are less affected by the regulatory environment of the Greek economy, either because they operate almost completely outside the Greek jurisdiction and administrative reality, for the case of shipping, or because they draw their competitive strength largely from the geographical attractiveness and the cultural heritage of Greece, as is the case for tourism.

These pieces of evidence manifest themselves in the compelling case for the low competitiveness of the Greek economy that is documented by a number of surveys (Fig. 9). The impressive part to note here is that a wide selection of different surveys, including those that measure governance and corruption, rank Greece in a roughly similar way even though they often use different methods that are either based on the evaluation of hard evidence, the responses to questionnaires, or a combination of both (Fig. 9).

Facets and Evidence of Institutional Inefficiency and Poor Governance

The OECD Regulation Database, the World Economic Forum competitiveness survey, the World Bank “Doing Business” and Governance Indicators, and the European Commission estimates (EU 2002, 2006), to name a few, all find that in Greece the administrative burden is also exceptionally high (Fig. 10), that regulation of markets is excessive, that government intervention limits competition as well as resource allocation and pricing decisions in crucial network industries, and that the regulation of professional and legal services (Figs. 11 and 12) is high as far as entry and price setting is concerned. At the same time, qualitative standards are excessively lax (Paterson et al. 2003) and that the business environment, as an aggregate, is unattractive.

These findings are complemented by more general statements that indicate weak institutions, poor governance (Kaufmann et al. 2005), and high levels of corruption that seem to follow as a consequence of the high administrative burden and the poor governance (Ackerman 2006).

As a matter of fact, the magnitude of the weaknesses documented by these pieces of evidence matches the size of the competitiveness deficit documented for Greece by the inflation differential with the eurozone, the current account deficit, and the low level of FDIs. It has to be added that, not surprisingly, Greece is found to be the OECD country which has the most to gain from rectifying these documented deficiencies, like product market regulation (Conway et al. 2006), in terms of

increased productivity. This performance can be labeled “dismal” not because of its absolute level, but because of the large discrepancy between the performance of the country on all these aspects

and the per capita GDP that it has achieved in the past years. In particular, following the strong performance till the 1970s and the strong performance of the past years, per capita GDP is

Efficient Market, Fig. 11 Regulation in professional services (Source: OECD indicator for regulation in professional services, 2007)

Efficient Market, Fig. 12 OECD indicator. Regulation of legal services, 2007 (Source: OECD. 6 = most stringent)

relatively close to the per capita GDP of the other OECD and EU member countries. And while Greece remains among the poorer members of these groups, it still can distance itself clearly from most other countries that do not participate in these two groups of privileged countries. On the other hand all the other performance indicators are clearly much weaker than the performance of all other OECD and EU member countries. Here Greece clearly is placed, repeatedly, in the middle of the sample of all the countries in the world, and not in the top 20% of the countries, as is the case with per capita GDP. Greece, ultimately, emerges as a country with almost first-class per capita GDP – until at least 2009 – but clearly second-class governance, institutions, business environment, and corruption (Fig. 13).

The factors that were analyzed previously and that document why Greece grew so fast in spite of these shortcomings can also reconcile the recent performance of Greece with the now extended literature, mainly of OECD Economic Department Working Papers (an indicative selection of related OECD and non-OECD related publications is OECD (2007a), Conway et al. (2006), Bassanini and Duval (2006), Nicoletti and Scarpetta (2005, 2006), Conway et al. (2005), Bassanini and Ernst (2002), Scarpetta and Tressel (2002), Scarpetta et al. (2002), Nicoletti and

Scarpetta (2003), OECD (2003), Nicoletti et al. (2001), Conway et al. (2006)), which directly link the performance of an economy with the quality of the regulatory framework and the prevalence of competitive markets. In a similar way one can reconcile also almost all of the other weak performances of the country that range from research and innovation (Bassanini et al. 2000) to the protection of the environment, the quality of public health services and schools, and the performance of the higher education system (Bassanini and Scarpetta 2001; Mitsopoulos and Pelagidis 2007a; OECD 2007b). Even the weak performance of the judiciary which we will present below in section “[Last but Not Least: Inefficiency of Justice](#)” can be ultimately linked to this pattern (Mitsopoulos and Pelagidis 2007b; Djankov et al. 2002).

The Paradox of the Underlying “High Labor Productivity” in a Low Competitiveness and Inefficiency Context

The result of the strong demand growth that is not driven by an increase in domestic supply that follows from an increase in employment (Fig. 14) directly affects the reliability of

Efficient Market, Fig. 13 Corruption and Regulation

Efficient Market, Fig. 14 Employment ratio for the population over 15 years of age

Source: OECD Productivity Database and OECD International regulation database

Efficient Market, Fig. 15 The scale of the indicators is 0-6 from least to most restrictive

productivity indexes that measure GDP to labor input – and that give a % of around 2.5–3% for Greece during these years – in various forms. This follows as the increase in the numerator (GDP) matches a restrained increase in the denominator (as can be seen in Fig. 14), thus measuring a large increase in the productivity per worker or per hour worked, in spite of the dismal performance of the Greek economy as measured by the rigidity index of relevant product markets (Fig. 15). It follows from the previous exposition that the use of such indicators is not correctly capturing the variety of the parameters that shape the performance of the

Greek economy during the past decade, often depicting Greece in a position that does not favor the drawing of reliable conclusions. This gives also an explanation to the puzzle of having on the one side high GDP and productivity rates and on the other side low competitiveness with twin deficits. At least to the extent, we take into account only domestic forces and not taking into account factors such as euro's overvaluation (at least to the extent that Greece's trade takes place with outside EU partners (around 50% of total)) and the asymmetric demand shocks.

Efficient Market, Fig. 16 State control. Involvement in business operation (Source: OECD. Index scale of 0–6 from least to most restrictive)

Efficient Market, Fig. 17 State control – price controls (Source: OECD. Index scale of 0–6 from least to most restrictive)

In this context, it is worth looking more on some other aspects of institutional rigidities which complement very well low competitiveness. Figure 16 summarizes product market regulation regarding state control through the involvement in business operation. Once again Greece appears to both have the most stringent

state involvement in the operation of businesses and to maintain these practices throughout the past decade.

Figures 17 and 18 concern the state involvement in business operations via price controls or the use of command and control regulation. “Command and control” includes a lot of

Efficient Market, Fig. 18 State control. Use of command and control regulation (Source: OECD. Index scale of 0–6 from least to most restrictive)

Efficient Market, Fig. 19 Employment protection legislation (However, the above data does not include the so-called shadow economy, which in the case of Greece it is estimated around 20–30 % of the official GDP. The “black

labour market,” as part of the shadow economy, includes a significantly flexible labour market that excludes employees from trade unions’ membership, social protection and insurance, working rights, etc.)

administrative mechanisms of hindrance of entrepreneurial activity/organization, in sectors such as “road and railway transports” and retail trade.

Product market rigidities are of critical importance for rigidities in the labor markets as well. Figure 19 shows Greece among OECD countries

with the highest employment protection legislation (EPL). It should be noted here that the market for nonpermanent, temporary employment in Greece is the main reason for the exceptional rigidity of the Greek labor market overall but that the market for permanent contracts is also

relatively rigid when compared with other OECD countries.

These kinds of structural institutional rigidities/inefficiencies constituted a true cost to society in the environment of a noncompetitive economy like the Greek economy. It meant and led to the exclusion of many others from the labor market, and especially the young that seek salaried labor. Under 26 years old unemployment was more than 35% and 20% for women and men correspondingly even before the crisis. This should be read as underutilization of a dynamic labor force and should not be considered solely as a major social or ethical issue.

We mentioned extensive regulation of markets, high administrative costs, a business environment that is not favorable to entrepreneurship and, in the end, weak convergence and widespread corruption as drivers and cause of this low competitiveness and low efficiency, in spite of the reforms in the credit and telecommunications markets and the benefits accruing from EMU accession. Greece emerges, therefore, to benefit from certain reforms in terms of potential output because of the nature and importance of these positive developments, while it retains other, also significant in importance and magnitude, weaknesses that undermine the long-term growth potential of the country. These weaknesses are ultimately described as “rigidities and inefficiencies, weak non-independent institutions and governance,” and their proliferation was deeply built in the

equilibrium that was formed between the interest groups that accrued the rents that they secured through the regulation of markets and the inflation of the administrative costs (Pelagidis and Mitsopoulos 2009). One could also argue that the strong growth of the past years has also made the need for further reforms less pressing.

Last but Not Least: Inefficiency of Justice

The weak performance of the judiciary, which we present very briefly below, can be ultimately linked also to this pattern (Mitsopoulos and Pelagidis 2007b; Djankov et al. 2002).

This unfortunate picture refers to cases that are quite old; therefore, the deterioration in the past years of the indirect measures of the time needed to dispose justice used in Mitsopoulos and Pelagidis (2007b) suggests that the cases that now enter the system may face even worse prospects. In particular, Fig. 20 shows that the ratio of cases that have not been heard to the sum of cases that are either pending or were introduced for the first time in the year has increased in upper civil courts from about 25% in 1997 to over 60% in 2005. The deterioration is visible, but less dramatic, in appeals courts and lower civil courts. Also, as shown in Fig. 21, for civil courts the appeal rate has increased slightly from 1997 to 2005.

Efficient Market, Fig. 20 Unresolved and postponed cases to total cases introduced

Efficient Market, Fig. 21 New introduced to appeals courts to concluded by first instance courts

Efficient Market, Fig. 22 % of cases first filed from the latter data of the range and till the latest date of the range. Cases to be retried

We also note in our sample in Mitsopoulos and Pelagidis (2010) for the Greek Supreme Court (*Areios Pagos*) some extreme delays in the process of serving justice (Fig. 22). Twenty percent of our cases have not been settled after almost 10 years since they were first filed, and even for these cases the process will be delayed for at least another year till the appeals court issues a new verdict. Sixty-five percent of the cases await a new verdict from the appeals court in spite of the fact that they were first filed between 5 and 10 years ago. On average, at the end of the year 2006, the cases tried by the *Areios Pagos*, and that were

marked for a retrial, were 6.5 years old. We also find a small but not insignificant number of cases, 8% of our sample, in which we document repeated appeals to the civil *Supreme Court*. These originate among the 40% of all the cases that have been retried by the order of the *Areios Pagos*. It seems that for a number of these, the new decision of the appeals court, or the court that tries in its place, is challenged anew by one of the involved parties in front of the *Areios Pagos*. While the total number of these cases is small, about 8% of the total, they are about half of the cases that were initiated more than 12 years before 2006 and about one fourth of

the cases that are over 10 years old. This indicated that there is a small, but non-negligible, chance that a case will get entangled in a process of repeated retrials, and this process ensures that no final verdict is obtained for at least a decade. Our sample contained two cases that were judged for the third time by the *Areios Pagos* and thus are due to get tried for the fourth time by the appeals court, and one case where the second verdict of the *Areios Pagos* got challenged and was directly brought again to the court for retrial.

Such delays also apply to cases in which the Supreme Court reaffirms the decision of the previous court. Taking a random sample of 100 of these cases from the year 2006, we see that these cases, which form about 60% of the cases in the year 2006, were on average over 7.5 years old at the time the decision of the *Areios Pagos* was published. And while 70% of these cases was less than 7 years old, a significant 30% was older than 7 years with one case being first introduced almost 26 years ago and another case 33 years ago (Fig. 23). About 25% of these very old cases, which were first introduced more than 7 years ago, were cases that had been retried by the appeals court before, after a previous order to do so, but 75% of these old cases simply proceeded very slowly.

These long delays in the process of official arbitration are not caused because one of the involved parties is not satisfied with the outcome, say because the height of the compensation awarded did not meet its expectations. They are caused because the lower courts either do not follow procedures properly or because they ignore, or misinterpret, laws which is an objective measure for the low quality of the decisions that are taken by the lower courts. In itself though, the use of the appeals process for error correction, as opposed to first instance and appeals courts decisions that do not make mistakes, does not provide by itself information on the quality of the judicial system, as explained by Shavell (1993).

Measuring the quality is curtailed by the fact that we have a complete sample only from *Supreme Court* decisions that do judge only the lawfulness of the preceding court decisions, as is appropriate for a civil law country. Also, since we are not always informed about the full content of all the preceding court decisions, that is, both the appeals and first-level court, or in the case of previous retrials the content of the initial court decisions, we cannot construct measures that compare the initial with the subsequent decisions. Furthermore, the structure of civil law does not permit judges to commit errors that may be

Efficient Market, Fig. 23 % of cases first filed from the latter data of the range and till the latest date of the range. Cases reaffirmed

brought before the highest court that we may use to pinpoint a low quality of court decisions that refer to issues like the height of compensation. Therefore, we are left once again only with a measure of time that allows us to measure the time needed to serve finally justice. As in our previous work (Mitsopoulos and Pelagidis 2007b), where we employed an indirect measure for time, we find again, using this time a direct measure for the time needed to dispose justice, that in Greece justice is served often with delays that are excessive and which undermine the usefulness of the official arbitration mechanism.

The 2010–2013 “Troika Period”: Reforms for Achieving Efficiency

Below we offer a list of reforms already implemented by the Greek government in the context of the conditionality programs agreed with the troika and the creditors of the country during the period 2010–2013. The list is not exhaustive albeit representative. Reforms are leading the country towards a much more efficient economic structure.

Labor Market Reforms

- Significant reforms for the private sector from 2010 (reduction of severance payment, relaxing of layoff limits, activation of tools to reduce individual salaries, possibility to bypass general wage agreements at the firm level) have increased downward wage cost flexibility.
- Even more significant reforms tied down in MoU2 (rationalization of mediation process, reduction of minimum wage, and impact of sectorial and other agreements).
- More fine-tuning reforms rumored for 2013–2014.
- Much lower minimum wage.
- Large reduction in firing costs for high earners.
- Redefining threshold for group layoffs.
- Removal of all impediments to conclude wage agreements at the company level.
- Significant changes in the mediation process.
- A very important impact of these in the reality behind average labor cost indexes.

In the end, these reforms do establish a truly flexible and efficient labor market in Greece.

Fiscal Reforms

- Wide ranging social security reform
- Large cuts in public sector salaries and salaries of public utility companies
- Healthcare reform (online prescriptions, pricing of medicine, etc.)
- Reforms in budgeting and fiscal reporting
- Very large, across the board, tax increases (albeit with a significant inflationary impact)
- Accelerating drive against tax evasion

Structural Reforms (selectively)

- Licensing process and spatial planning reform (about 40% complete)
- Road haulage deregulation (about 50% complete)
- Cruise ship home porting regardless of flag
- Already some deregulation in professional fees and obligatory purchase of services (notary public, lawyers for small real estate transactions, company start-ups, fees of engineers, trademark submission without lawyer attendance, sale of baby milk outside pharmacies, etc.)
- Establishment of one-stop shops for company creation and gradual improvement in their operation (yet complicated process design does not work well)
- Export facilitation (abolishing obligation to register in “exporters registry,” a strategy to boost exports, link Piraeus port terminal operated by COSCO with rail network, etc.)

An Indicative List of New Taxation Since the First Memorandum 2010

- Multiple abolition of tax exemptions
- Increased of annual estate tax, up to 2% of administratively set value, and then additional estate tax through electricity bills
- Multiple VAT increases
- New personal income taxation law with higher rates, lower tax-free income
- 3 tax increases on tobacco and alcoholic beverages and VAT increase on nonalcoholic beverages

- Further increase of tax on mobile communications – highest in the EU
- 3 gas/petrol tax increases
- Multiple increases of taxes on electricity, especially for businesses – now probably highest energy prices in the EU for industry
- Introduction and increase of luxury tax
- Recurrent extraordinary tax on profitable companies and increased tax on dividends
- Introduction and increase of recurrent extraordinary tax on high personal incomes
- Tax on banks and increase of tax advancement
- Tax on TV advertisements
- Tax on violations of building permits
- Green tax
- Income tax on leased cars and private sector company cars (but not government official cars!!!)
- Introduction and then increase of tax on assumed income
- Increase in train and bus tickets
- Tax to avoid antismoking ban
- Fee to access hospitals
- Highest recurrent real estate taxes in the OECD

Since the initiation of the conditionality programs in 2010, and after two revisions and a debt haircut to private creditors in 2012, the improvement of the business environment, the remove of red tape, and the creation of a level playing field through the removal of restrictive to competition laws have been rather a second priority both for the Greek governments and for the official lenders of the former, when compared with tax increases and labor market reforms and at least for the two first years of the program implementation. While this has been changing slowly during 2013–2014, with the official lenders now demanding from the Greek government progress on these issues and while they now offer also extensive technical assistance, it must be noted that the delay in the acknowledgment of the importance of such measures may yet prove to be crucial. In sum, more reforms are needed in the domains of product and professional markets to increase thoroughly efficiency. Below one can find a few suggestions on this issue.

More Reforms for Efficiency

- Complete licensing, business park legislation, etc.
- Complete professional services deregulation
- Rationalizing the complex system of third-party payments
- Rationalizing regulation in the energy sector
- Rolling out the privatization program in a more aggressive way, emphasizing assets crucial for competitiveness like ports and not gambling
- Structural reforms that will improve the business environment and that are yet to be identified
- Emphasis at last in deregulating product and professional markets
- Last (but not least), a (meaningful) tax reform which will not include today's overtaxation

Electoral Systems

Guido Ortona

Dipartimento di Giurisprudenza e Scienze Politiche, Economiche e Sociali, Università del Piemonte Orientale, Alessandria, Italy

Definition

Electoral system. An electoral system is the set of rules employed to summon a representative body on the basis of the preferences expressed by a group of electors, through a given voting procedure. The chapter compares electoral systems with reference to the election of a Chamber of a democratic Parliament.

Introduction and Overview

An *electoral system* is the set of rules employed to summon a representative body on the basis of the preferences expressed by a group of electors, through a given voting procedure. This definition applies to many settings, from parents' circles to supernational organizations; in this survey we will deal only with the election of a Chamber of a Parliament. We will also limit the discussion to the context that is usual in present-time democracies; hence we will assume (a) that all voters express the same number of votes (very often one, but there are many exceptions) and (b) that within the set of allowed alternatives, there are no constraints on the choice made by the voters. The votes are cast in an *election*, and for obvious reasons the election usually takes place in different *districts*; there are however several countries, not all of them minuscule, where there is a unique nationwide district. This is the case, for instance,

of Israel and the Netherlands. The number of the Members of Parliament (normally shortened to MPs) to be elected in each district is the *district magnitude*.

A meaningful classification of electoral systems may be obtained through the crossing of two dual dimensions, *nominality* and *plurality/proportionality*. A district may elect one MP, in which case it is *uninominal*, or more, and it is *plurinominal*; and the Seats may be assigned either *proportionally* to the valid votes obtained by each list of candidates (usually a *party*) or according to the number of votes received by each candidate, in which case the system is *majoritarian*. A uninominal election is obviously majoritarian, while a plurinominal one needs not being proportional but usually is, hence the frequent identification in the everyday political debate of uninominal elections with the use of the majority rule and of plurinominal ones with proportionality.

The electoral law plays a fundamental role in the functioning of a democracy, and it is a main determinant of the perspectives, and hence of the strategies, of both incumbent MPs and challenging candidates. No surprise, then, that the electoral law may be subject to changes that may easily be dramatic and frequent. Comprehensibly, this is particularly true in times of political and economic turbulence; this entry is being written in such a period, hence the reader is reminded that the data quoted in it are those of the last months of 2016.

An authoritative source (IDEA 2005) proposes the following classification of the electoral systems actually employed in at least one country at the time of its publication:

Plurality/Majority systems: Plurality (also labeled first-past-the-post), two-round system, alternative vote, block vote, and party block vote

Proportional representation: List proportional (open or closed), single transferable vote

Mixed systems: Parallel, mixed-member proportional

Other: Single nontransferable vote, limited vote, and Borda count

The Mixed member proportional system is the system in use in Germany; the author of this entry

suggests that it should be considered a member of the proportional representation family. More on this in section “[Proportional Systems](#).” The list is not exhaustive, more so if one considers also the systems that have been defined by the doctrine, those employed at a sub-parliamentary level, and the variants within a given system. What is remarkable is the absence, among the plurality systems, of the Condorcet system. The Condorcet system qualifies as the best of the family because if the choice is not the Condorcet winner, then there exists another one that a majority prefers to it. (The *Condorcet winner*, i.e., the alternative chosen when the Condorcet procedure is in use, is the one that is preferred by a majority in dual contests against each of the others in turn. It may not exist, but in large electoral settings this is a very rare occurrence, and it may be taken into account via a suitable tie-breaking rule.) The doctrine assumed the Condorcet system as the benchmark to be employed to assess comparatively other plurality systems, since the very beginning of the quantitative comparison of electoral systems up to now (see Merrill 1984, and Diss and Doghmi 2016). Not surprisingly, normally the best system results being the *Borda rule* (see below). The implementation of the Condorcet rule requires computing facilities not available until relatively recently, yet the increasing introduction of electronic voting devices makes it a reasonable option. No country, however, is presently considering its adoption.

In this entry we will describe the aforementioned systems in some detail (sections “[Majoritarian Systems](#),” “[Proportional Systems](#),” and “[Mixed and Other Systems](#)”), and then we will move to the problem of the choice of the electoral system (sections “[Majority or Proportionality? Theory](#),” “[Majority or Proportionality? Evidence](#),” and “[Electoral Reforms and Public Opinion](#)”).

Majority, Proportionality and History

The most relevant difference among electoral systems is the fundamental principle upon which they are based, that is whether they are *majoritarian* or *proportional*. Before proceeding, it is necessary to

make it clear a very basic point, which is not always duly considered in the literature, let alone in the political debate. A majoritarian system assumes that the citizens of a particular constituency have common interests and/or opinions and that they are called to choose a delegate to represent at the best their interests and/or opinions, in the spirit of the *theorem of Condorcet*. (The theorem states that the probability of making the best choice increases with the number of deciding subjects, provided – inter alia – that there is a choice that is actually the best for each of the subjects.) A proportional system assumes instead that the community of interests does not concern a given location but a given *social group* throughout the territory. At the district level, the communality of interests may not exist, and if it exists, it is inferior to other, nonlocal communalities. It follows that the representation must be divided (proportionally) among the various groups, in order to reproduce the articulations of the society in a manageable scale. This is why Parliaments with an ancient origin are typically majoritarian, like those of the UK and of the USA, while modern ones are typically proportional (for a discussion of this point based on historical evidence, see Ahmed 2013). Also, this is why the majority of present-time scholars favor proportionality (see Bowler and others 2005).

Worldwide, in 2016, 85 Parliaments were proportional, 62 were majoritarian, and 34 were mixed (including Germany); the use of other systems was not uncommon, as they summed to 69, divided among nine different systems (data from the ACE Electoral Knowledge Network, <http://aceproject.org/>). Proportional systems are most largely employed in Europe, where 35 Parliaments (including Germany, see below) out of 46 belonged to the family.

Majoritarian Systems

The simpler and most used majoritarian system is uninominal *plurality*, also labeled *first-past-the-post* (FPTP); it is adopted in the UK, USA, India, and in many other countries of British tradition. There are as many districts as MPs to be

elected, and in each district the candidate who obtains a plurality of valid votes is elected. The *two-round system* is adopted in France and in several countries formerly in the French empire. The districts are uninominal, but if no candidate obtains a *majority*, there will be a second round involving a subset of the candidates (in France those who got at least 12.5% of valid votes, or the first two if none exceeded this threshold). The other majoritarian systems are much less in use. With the *alternative vote* (also known as *instant-runoff vote* or *transferable vote*), the districts are uninominal too. The voter is requested to rank all the candidates according to her/his preferences or some of them. In the first round only the first preferences are considered, and a candidate is elected if she/he obtains a majority. If none gets it, the candidate with less votes is excluded, and each of her/his votes is transferred to the second preference of the voter. The procedure is iterated until the majority arises. The system is employed in Australia and in other countries in Oceania; in 2011 a referendum rejected its adoption in the United Kingdom. *Block vote* and its variant *party block vote* are majoritarian but plurinominal. In the first version each voter may vote for several candidates, and those with more votes are elected; in the second each voter votes for a party, and the party with more votes wins all the seats of the district. The first variant is in use in Lebanon and Mauritius, but the most extreme application occurs in Monaco, where 16 MPs out of 24 are elected with this system, and each voter may cast up to 24 votes. The second variant is in use in Cameroon and Chad.

Proportional Systems

A *pure proportional system* (one national district, no seat assignment threshold) is in force only in 10 countries, that is Colombia (Senate only), Fiji, Israel, Mozambique, Namibia, the Netherlands, Paraguay (Senate only), Serbia, Slovakia, and South Africa. In any case, the seats are assigned to each party according to the share of valid votes obtained. With proportionality there is a problem with the rounding of the results, that

may be serious if the district magnitude is small. Most countries employ the *D'Hondt rule*, a member of the family of *highest average methods*. The number of valid votes of each party in each district are divided by successive integers, starting with 1, and the M largest ratios, where M is the district magnitude, individuate the elected candidates. There are several variants; the one most in use is the *Sainte-Laguë rule*, where only odd integers are considered, what favors the smaller parties. *Largest remainder methods* are much less employed: their principle is that the remainders determine the seats to be assigned to each party after that each one obtained the number of seats given by its integer share of votes. The party list may be either *closed*, when the voter may only choose the party, or (partially or totally) *open*, if she/he may also indicate one or more preferences within the list.

The real proportionality depends crucially from the *district magnitude*. Lijphart suggested that the following formula:

$$T = 75 / (M + 1)$$

where T is the implicit percent threshold and M is the district magnitude may roughly indicate the implicit threshold that the magnitude introduces. For instance, a district magnitude of 9 would produce (roughly) the same results of a district with a threshold for participating to the assignment of seats of 7.5%.

There is a commonsense wisdom that a trade-off exists between *proportionality* and *governability*: a not-constrained proportional vote would produce a plethora of parties, what would make it difficult the summoning of a stable and effective government. This assumption has been criticized by several authors, both on empirical and theoretical foundations, and actually it does not enjoy a sound theoretical basis (see f.i. Migheli et al. 2014). The reason is that a majoritarian system tends to produce few large parties, usually two, that include interests and opinions that may be highly different if not contrasting, in the logic of the so-called *Law of Duverger*; what may induce a bargaining *within* a party that may be as engaging as that *among*

parties in proportionality. (The Law of Duverger is not a law but an empirical regularity, not very often respected in full, according to which plurality produces a two-party system.) Nevertheless most countries adopt some correction to pure proportionality; these corrections are of three types, a *participation threshold*, by far the most common, a *majority prize*, and a *reduced district magnitude*.

Participation thresholds (that establish that a party will not get seats unless its share of valid votes is greater than the threshold) range typically around 3–5%, with Liechtenstein (8%) and Turkey (10%) outlying. As stated above, a threshold is in use in most proportional countries.

The majority prize is present in Greece and Italy (and in san Marino). The party (or the coalition of parties) that obtain a given share of votes obtains additional seats. There are some historical precedents, like the *Law Acerbo* (1924, from the name of its author), that opened the way to the electoral triumph of Mussolini and the so-called *Loi Scélérate* in France and *Law Truffa* in Italy (“scélérate” meaning wicked and “truffa” meaning fraud), respectively, in 1951 and 1953. Both the historical precedents (and the names they were popularly labeled in the last two cases), and the inability to resolve a political stalemate in the two countries concerned at present, justify clearly enough the limited consensus that this system enjoys among the scholars. In Spain the districts are usually small, what, as we saw, reduces the proportionality; again the results in terms of governability are apparently poor.

The *single transferable vote* aims at preserving the vote-for-a-person feature of majoritarian systems while at the same time assigning the seats proportionally. This is why it is highly appreciated by the English and American literature; however, by its very nature, the system requires small districts, what makes its proportionality limited. It is in use only in Australia (Senate), Ireland, and Malta. Omitting minor technicalities, its typical structure is the following. Suppose a district magnitude of M , say, 5, and N valid votes, say, 1,200. Each voter must rank all the candidates according to her/his order of preference. All the candidates that are ranked first by at least 201 voters are

elected; this is because at most 5 candidates may obtain so many first preferences (and in general $1 + M/(N + 1)$ first preferences). Suppose now that a candidate obtains 301 first preferences. 201 are “used” to win her/his seat, while 100 (chosen at random) are transferred (whence the name of the system) to the *second* preference, and the procedure is iterated until 5 MPs are summoned.

Mixed and Other Systems

A *parallel system* is in use when some MPs are elected with a system and the others with another one (or possibly more); the two systems are normally a majoritarian and a proportional one. A parallel system is supposed to guarantee a representation, albeit with a reduced share, to all the parties whose share of votes exceeds the established threshold, while at the same time producing an enhanced governability thanks to the majoritarian principle. Several countries adopt a parallel system, including Russia, Mexico, Hungary, the Philippines, Thailand, Venezuela, Japan, and South Korea. Instead, a *mixed-member proportional system* maintains the proportionality while requesting also a uninominal vote. The most relevant example is Germany; voters vote for a candidate in a uninominal majoritarian district and at the same time for a party in a large proportional one. The seats to be assigned to each party are determined by its share in the proportional vote, but the candidates obtaining a plurality in the uninominal districts are elected anyway. If a party obtains, say, 200 seats in the proportional vote but it wins in 205 uninominal districts, the total number of MPs is increased correspondingly. (In Germany a 5% national threshold is in force, but this threshold is not requested for a party that wins in at least 3 uninominal contests.) As a result, the system is not that different from an open list proportional one. New Zealand and Bolivia also employ it.

The *single nontransferable vote* is the application of the majority rule to plurinominal districts. Each voter has one vote, and the M candidates with more votes are elected, M being the district magnitude. It is in use in some Asian countries,

among which Indonesia (Senate). The *limited vote system* is analogous, but the voter may express more than one vote, albeit less than the district magnitude; it is adopted in Spain for the election of the Senate. Finally, the *Borda count*, despite the appealing theoretical properties of the system, is employed only in Slovenia, and for two seats only, and in Nauru. (Each voter ranks the candidates, giving 1 point to the first, 2 to the second, etc.; the points are summed, and the M candidates with less points are elected, M being again the district magnitude.)

Majority or Proportionality? Theory

The political doctrine made a lot of efforts to individuate the advantages and the flaws of the different electoral methods. We will consider only the comparison of the two grand families, that of the proportional systems and that of majoritarian ones. Here is a (non-exhaustive) list. For a more detailed discussion of the points listed below, see IDEA (2005), and the sub-site *Electoral Systems* of the site of ACE (Electoral Knowledge Network) or, obviously, the (enormous) scientific literature.

Majority/Plurality, Advantages

- (a) It tends to produce a one-party government, what enhances both stability and governability.
- (b) Symmetrically, it produces a strong and realistic opposition.
- (c) It encourages the parties to represent broad arrays of interests.
- (d) It tends to exclude extremist parties from the Parliament.
- (e) It forces the parties to choose credible and respected candidates and allows voters to choose individuals instead of parties.
- (f) It opens the way to independent candidates.
- (g) It is simple to understand.
- (h) It enhances the accountability of the government, as the responsibility for unpopular choices cannot be easily concealed.
- (i) It promotes the representation of the local interests.

Majority/Plurality, Flaws

- (a) Many voters will not be represented.
- (b) It may assign all the power to a party that may well have a limited consensus, what could create serious problems especially in divided societies.
- (c) It excludes small parties, and hence, easily, minority groups from obtaining a representation.
- (d) It spoils many votes, possibly even the majority of them.
- (e) As typically there will be two candidates, both close to the center of the political spectrum, many voters will not find a suitable candidate, mostly if the spectrum is large.

In addition, some of the advantages may actually be considered flaws.

- (f) A one-party government may exclude the possibility of the establishment of an effective “social contract” among contrasting groups of interest.
- (g) An extremist party is possibly more dangerous if it is excluded from the Parliament.
- (h) A candidate may be locally strong not due to her/his moral and intellectual standing but to her/his link with a lobby or a powerful pressure group (or person).
- (i) There will be a limited competition within the large partitions of the electorate, usually “left” and “right,” because each partition will candidate just one person in each district, what can reduce the quality of the candidates.
- (j) A perceived excess or responsibility may induce inaction.
- (k) Inaction may also be the consequence of the necessity of composing contrasting interests in a party forced to look for the sustain of different social groups (as suggested above in section “[Proportional Systems](#)”)
- (l) A proportional system adopting the D’Hondt rule, or even better the Sainte-Laguë rule, may propitiate independent candidacies not less than majority.

Proportionality, Advantages

- (a) It is the “natural” system, because it reproduces the overall society in a manageable

assembly (see above, section “[Majority, Proportionality and History](#)”).

- (b) It creates homogenous parties, thus avoiding the problems referred to above under letter *k*.
- (c) It puts the political transactions more in the open, as it will be more *among* parties than *within* parties.
- (d) It propitiates the representation of minorities.
- (e) It offers the voter a broader choice, thus enhancing the competition among parties.
- (f) It allows more stability and less traumatic changes, as the governments will typically be made by coalitions.
- (g) It strengthens the link between citizens and politicians, as it offers the voters a larger choice.

Proportionality, Flaws

- (a) Coalition governments may induce a stalemate in the activity of the government.
- (b) A too fragmented system of parties can make the political bargaining cumbersome.
- (c) Small centrist parties will be given an excess of power, what reduces the actual proportionality of the system.

Again, some advantages may actually turn into pitfalls.

- (d) The stability may correspond to an excessive entrenchment in power of large centrist parties.
- (e) Extremist parties may enjoy a undeserved status.

The preceding summary indicates that the typical features of the two meta-systems may easily be either an advantage or a flaw, according to the circumstances, what, arguably, makes it difficult to assess their nature on a general basis. Consequently, the support for either system is usually lexicographic. Those who prefer majority claim that the most relevant advantage of the system, i.e., the enhanced governability given by a reduction of the deciding subjects, is sufficiently important to make it preferable despite its flaws, while those who favor proportionality claim the same with reference to representativeness.

Majority or Proportionality? Evidence

A sound quantitative comparative assessment is made difficult, if not impossible, by the lack of sufficient data. The econometric literature is vast, yet its results are contradictory, as they rest too strongly on the choice of data and on unavoidable simplifying assumptions. However, on a less sophisticated basis data offer only a limited support to the basic argument in favor of majority. Already a couple of decades ago, some authors, like Lijphart (1999) and Farrell (1997), noticed that there is no convincing evidence of the superiority of plurality in term of governability. In Europe, at the beginning of 2017, the two large nonproportional countries (UK and France) apparently faced serious problem of governability, and this is also the case of the three less proportional countries among the proportional ones, that is Spain, Italy, and Greece. Actually, two main tenets in favor of the argued greater governability of majority/plurality systems are not confirmed by facts. The first is the blackmailing power of small centrist parties: in the two more proportional countries of Europe, Italy (1948–1993) and the Netherlands (since 1946), the possibility for a small party to blackmail a majority through the menace of leaving has been a very rare occurrence. The likely reason is that a power rent induces the birth of further small centrist parties, until the rent is dissipated, as first suggested by McGann, Enschedé, and Moran in 2009 and as confirmed by data.

As a result, quite a consensus has been reached among scholars that proportionality is preferable, as we noted in section “[Majority, Proportionality and History](#)” above, yet this consensus is far from being unanimous, and the debate is far from been conclusive on what proportional system should be deemed the best one. Probably a plurality of scholars would suggest a list proportional system with a threshold. (A recent contribution pointing to this result is Raabe and Linhart 2017; albeit, as we noticed, cross-country comparisons are risky, the result is strengthened by having the authors taken into account a very large set of data, 590 elections in 57 countries.) As a general conclusion, however, it is very likely that no system may be assumed to

be the best one for all the existing democracies, because the specific features play a very relevant role. Probably there are systems which are out of date or inferior to others in many if not most cases, yet Katz (1997, p. 308) has surely a point when he claims that what is the best electoral system depends on “who you are, where you are, and where you want to go.”

Electoral Reforms and Public Opinion

Broadly speaking, an electoral reform may be either the result of an attempt to make the system closer to the expectations of the citizens or on the contrary of an attempt of the political élite in power to escape a greater control by the citizens, be it to defend some privileges or to enhance the governability. For instance, the first is the case of New Zealand, that in 1994 moved from plurality, as in the UK, to mixed-member proportionality, as in Germany; the second is that of Italy, where two successive electoral laws, in 2014 and in 2016, have been rejected by the Constitutional Court. Dissatisfaction with the political establishment makes it often appealing for the public opinion the proposal of a change in the electoral system. Survey data show that in the UK a majority would prefer to change to proportionality, but in Italy in 1993 a referendum introduced a parallel system, with a larger share for plurality, in lieu of the nearly perfect proportionality in force. (The proportionality was reintroduced in 2005.) Not surprisingly, the electoral system is more likely reformed in times of economic or social change. A source (Renwick 2011) lists 47 modifications of the electoral law across Western Europe from 1945 to 2008; only 5 occurred between 1960 and 1980.

It is difficult to disentangle the satisfaction (or the dissatisfaction) with overall politics and politicians from that with the electoral system, not to speak of the low number of observations available; hence the data on the attitude of the citizens are inconclusive. Yet, if we admit that the turnout may be a proxy for the relative approval of the citizens for their electoral system, there are hints that proportionality is more appreciated than plurality. This is what is suggested by the last

elections (at the end of 2016) in comparable countries of Europe. The turnout was 75% in Italy in 2013 and in the Netherlands in 2012, 71.5% in Germany in 2013, 66% in the UK in 2015, and 57% in France in 2012. The first three countries are proportional; the last two are not. That voter turnout is higher in proportional elections is also claimed by IDEA (2016, p. 36), as an overall result of the literature. Among others, Dalton (2008) confirms this guess at the textbook level. In addition, Renwick (quoted above) reports that out of the 84 changes of the electoral law made in Europe (including non-Western countries) between 1945 and 2008, 37 aimed at increasing the proportionality and 23 at reducing it (the remaining ones did not affect this side of the electoral rule).

Emissions Trading

Edwin Woerdman

Faculty of Law, Department of Law and Economics, University of Groningen, Groningen, The Netherlands

Abstract

Emissions trading is a market-based instrument to achieve environmental targets in a cost-effective way by allowing legal entities to buy and sell emission rights. The current international dissemination and intended linking of emissions trading schemes underlines the growing relevance of this instrument. There are three basic design variants of emissions trading: cap-and-trade (allowance trading), performance standard rate trading (credit trading), and project-based credit trading (such as domestic offsets, JI, and the CDM). These design variants are analyzed in terms of effectiveness, efficiency, and acceptance. It is also explained why emissions trading schemes may become inefficient hybrids of such design variants.

Synonyms

[Allowance trading](#); [Cap-and-trade](#); [Credit trading](#); [Permit trading](#); [Tradable emission rights](#); [Transferable discharge permits](#)

Definition

Emissions trading is a market-based instrument to achieve environmental targets in a cost-effective way by allowing legal entities to buy and sell emission rights.

Introduction

Emissions trading is a market-based instrument to achieve environmental targets in a cost-effective way by allowing legal entities to buy and sell emission rights. The term “emissions trading” is an umbrella concept for several design variants that differ substantially both in theory and in practice.

In one system, trade in emissions is carried out by firms subject to an absolute emissions cap, which is referred to as “cap-and-trade” or “allowance trading.” Examples are the US sulfur dioxide (US SO₂) emissions trading program, the European Union Emissions Trading Scheme (EU ETS), and the California Cap-and-Trade Program to cost-effectively reduce greenhouse gases, such as carbon dioxide (CO₂), as well as some of the Chinese CO₂ emissions trading pilots, including the one in the province of Guangdong.

The other system is based on trade in emissions carried out by firms subject to a relative emissions standard, which is referred to as “performance standard rate trading” or sometimes “credit trading.” Think of the early emissions trading schemes in the USA to flexibly maintain air quality standards, the (recently terminated) nitrogen oxide (NO_x) emissions trading scheme in the Netherlands, or the CO₂ emissions trading pilot in the Chinese city of Shenzhen.

Again another system is project-based credit trading, where an investor receives credits for achieved emission reductions at a domestic or foreign host. These emission reductions are measured from a baseline that estimates future emissions at a project location if the project had not taken place. Think of domestic offsets or the international projects of Joint Implementation (JI) or the Clean Development Mechanism (CDM) under the Kyoto Protocol on climate change.

This article is organized as follows. Section “[Emissions Trading: Theory and Practice](#)” discusses the concept and international dissemination of emissions trading. Section “[Emissions Trading Variants](#)” describes the aforementioned three basic emissions trading variants in more detail. Section “[Analysis of Emissions Trading Variants](#)” analyzes these emissions trading variants in terms of effectiveness, efficiency, and acceptance. Section “[Emissions Trading Hybrids: the Case of the EU ETS](#)” focuses on hybrids of the emissions trading variants by taking the EU ETS as an example. A summary is presented in section “[Summary](#)”.

Emissions Trading: Theory and Practice

In the previous century, law and economics scholar Ronald Coase (1960) postulated that trading emissions would improve the cost-effectiveness of environmental regulation. The economic concept of emissions trading was developed further by John Dales (1968). To explain this concept in an easy way, one could say that emissions trading resembles a waterbed. Suppose you would like to raise the water level at the head of a waterbed, then you would have to push down the water level at the foot of the bed. This is also how emissions trading works. One company can buy emission rights and may emit more, but the company selling the emission rights first has to reduce its emissions by an equal amount in order to make these rights available for sale. As a result the government can be certain, provided there is adequate monitoring and enforcement, that the emissions of all the companies together will not exceed the number of emission rights allocated in the emissions trading scheme. As a consequence, emissions trading is an effective tool for achieving emissions targets. Emissions trading is also efficient in the sense that companies can look for the cheapest way to fulfill their emission reductions obligations. The specific design of an emissions trading scheme determines its environmental effectiveness, economic efficiency, and political acceptability.

Emissions trading has gone truly global. Emissions trading schemes have emerged in North America, including the Regional Greenhouse Gas Initiative (RGGI) and the Western Climate Initiative (WCI) in the USA as well as the Québec Cap-and-Trade System in Canada. In Europe, there is the EU Emissions Trading Scheme (EU ETS) for greenhouse gases as well as the Swiss Emissions Trading Scheme. Oceania holds Australia's Carbon Pricing Mechanism (AUS CPM) and the New Zealand Emissions Trading Scheme (NZ ETS). Asia has the Tokyo Cap-and-Trade Program, seven emissions trading pilots carried out in China (for instance, in Beijing and Shanghai), a forthcoming Korea Emissions Trading Scheme, as well as a pilot in Kazakhstan. Moreover, Turkey, Ukraine, and the Russian Federation are considering the adoption of emissions trading schemes, as well as countries such as Thailand and Mexico (for an overview, see, for instance, ICAP 2014).

An interesting, recent development is the intended linking of some of these emissions trading schemes (Weishaar 2014). In North America, the California Cap-and-Trade Program has been linked to the Québec Cap-and-Trade System in 2014. The EU and Australia agreed on a pathway for linking the EU ETS and the AUS CPM in 2018 (although the latter scheme has been under fire in domestic Australian politics). The EU is also negotiating with Switzerland on linking the EU ETS with the Swiss ETS.

Emissions Trading Variants

There are three basic design variants of emissions trading:

- Cap-and-trade
- Performance standard rate trading
- Project-based credit trading

Cap-and-Trade

The cap-and-trade system (or allowance trading) imposes a cap on the annual emissions of a group of companies for a number of years. The emission rights are allocated to established companies for

the entire period either for free or through annual sale by auction (a combination is also possible). Newcomers and companies seeking to expand must purchase rights from established companies or from a government reserve, while a company closing down a plant can sell its emission rights.

Some examples are the US sulfur dioxide (US SO₂) emissions trading program initiated in 1995, the European Union Emissions Trading Scheme (EU ETS) for greenhouse gases set up in 2005, and some of the Chinese CO₂ emissions trading pilots, for instance, in the province of Guangdong, erected in 2013.

To introduce and start a cap-and-trade scheme, the legislator has to put in place the following design elements (Tietenberg 1980; Nentjes et al. 2002):

- Set a cap on total emissions per year for a group of emission sources, in advance, and for a range of successive years.
- Create allowances, entitling emissions equal to the total emissions cap.
- Distribute the allowances among group members, either by auctioning the allowances at predetermined dates or by handing out the allowances free of charge.
- Allowances can be traded freely.
- Monitor emissions per source and track the allowances.
- Check compliance over a past budget period (e.g., a book year) by comparing monitored emissions with the number of allowances handed over at the end of the period.
- Penalize noncompliance if emissions exceed the allowances, with a fine per lacking allowance that is a multiple of the market price of an allowance.

Performance Standard Rate Trading

Performance standard rate trading (or credit trading) is different from cap-and-trade. A system of performance standard rate trading is based (not on an emissions cap but) on a mandatory emissions standard adopted for a group of companies. The emissions standard dictates permitted emissions per unit of energy consumption or per unit of added value. In this system emission reduction

credits can be earned by emitting less than what is prescribed by the emissions standard. These credits can then be sold to companies that can use them to compensate their emissions in excess of the emissions standard which applies to them.

If the economy grows, the supply of credits also increases because companies do not operate under an absolute emission ceiling but have to observe a relative emissions standard. An energy-intensive company that expands production, or a newcomer entering the industry, therefore has a right to new emissions, as long as it obeys the emissions standard. This means that absolute emissions will grow. To prevent that from happening, the emissions standard can be strengthened (Deweese 2001; Weishaar 2007).

This system has been developed since the 1970s in the US Environmental Protection Agency (EPA) emissions trading program. A system of tradable nitrogen oxide (NO_x) emission reduction credits has been in place for energy-intensive companies in the Netherlands between 2005 and 2013. A system of tradable reduction credits can also be found in the CO₂ emissions trading pilot in the Chinese city of Shenzhen, launched in 2013.

Project-Based Credit Trading

Project-based emissions trading, like Joint Implementation (JI) and Clean Development Mechanism (CDM) projects under the Kyoto Protocol, can be seen as a variant of credit trading. JI relates to emission reduction projects in East European countries, whereas the CDM refers to such projects in developing countries. Both credit trading and emission reduction projects allow for the transfer of credits, but projects usually require pre-approval to check the environmental integrity of the project baseline. This is not necessary under credit trading where the baseline is existing environmental policy (like an emissions standard), so that compliance can be checked by the end of the year. Moreover, the firm which funds the reductions under credit trading is also the firm where the reductions are realized, but in the case of project-based emissions trading, three design options are available (Dutschke and Michaelowa 1999):

- Multilateral approach
- Bilateral approach
- Unilateral approach

In the multilateral approach, an international fund would be created in which private and/or public entities from industrialized countries are required to pool their investments. The bilateral model places more emphasis on private investment and market forces since project selection and implementation are left to the participants. In the unilateral model, a (legal entity within the) host government generates the credits on its own without foreign direct investment.

If such projects are not applied internationally, but domestically, the literature talks about “domestic offsets.” A domestic party then invests in a domestic project in order to generate credits that can be used by the former to meet certain emission requirements.

Project-based credit trading generates credits on the basis of the difference between baseline emissions and predicted (or actual) emissions at the project site. The baseline is an estimation of future emissions at the project site in the absence of the project. This baseline is thus a counterfactual that will never materialize.

Analysis of Emissions Trading Variants

What are the similarities and differences between cap-and-trade, performance standard rate trading, and project-based credit trading, and how do they perform in terms of effectiveness, efficiency, and acceptance? This is explained and discussed in the next subsections.

Effectiveness

Effectiveness refers to reaching the emissions targets in an emissions trading scheme. Cap-and-trade is environmentally effective because it imposes an absolute limit on total emissions. If monitoring and enforcement are in order, the emissions cap will be achieved. This is a very strong and important property of cap-and-trade. Effectiveness will only be a problem if emissions are not adequately monitored or if noncompliance

measures are not enforced. Emissions will then be higher than intended by the legislator. However, if the institutional capacity of a country is solid, cap-and-trade will reach effectiveness.

Performance standard rate trading may have a problem in reaching an absolute emission level for the industry to which the relative standard applies. As production and energy consumption rise, the emissions of companies bound by the emissions standard rise proportionally. This will not change if tradable reduction credits are added to the emissions standard. The only way to circumvent this problem is by strengthening the emissions standard. Firms could lobby against such a sharper emission requirement, unless the adjustment to the standard is automatically made.

Project-based credit trading is likely to invoke even stronger effectiveness concerns. There may be several plausible ways to calculate the baseline for emission reduction projects, in particular in host countries where domestic climate change policy is being developed or where such policy is absent. The problem is that the baseline emissions which would have occurred without the project will never be known when the project is implemented. Effectiveness can be undermined if future emissions are overestimated by inflating the baseline to claim more credits. This incentive is strongest for the investor and host under the CDM in developing countries that do not have a nationwide emissions cap. Even if credits are generated on the basis of genuine emission reductions achieved at the project location, emissions may still increase in the CDM host country outside this location (Jepma and Munasinghe 1998). The incentive to inflate the project baseline also exists for legal entities involved in a JI project in Eastern Europe, but not for the JI host party government with an assigned amount of emissions under the Kyoto Protocol since this government would run the risk of being in noncompliance by transferring too many credits.

Efficiency

Efficiency refers to the pricing of emissions so that consumers internalize the environmental damage. Sometimes efficiency is interpreted

more modestly as cost-effectiveness, which is about reaching the environmental targets at the lowest possible cost.

Cap-and-trade has “superior” efficiency properties (Tietenberg et al. 1999). In an emissions trading system based on emissions caps, each emission unit has a price and reductions in these units are profitable. From an efficiency point of view, it does not matter whether the emission allowances are allocated for free or sold at auction. If the company uses the free rights to cover its emissions, so-called opportunity costs are associated with them (Nentjes et al. 2002; Woerdman et al. 2008). The company then foregoes the opportunity to sell its allowances and misses sales revenues. The opportunity costs constitute a part of the cost price of the product. In a cap-and-trade system, each unit of emission has a price. Consequently, emission reductions in a cap-and-trade system are profitable regardless of the method by which they are achieved. It makes no difference whether such a reduction is achieved through cleaner exhaust gases, through cuts in energy consumption, or by limiting production. In a cap-and-trade scheme, there is an incentive to examine all emission reduction possibilities and to apply the least-cost option.

In a system of performance standard rate trading, companies that would have to make high costs to achieve the emissions standard will instead buy emission reductions from companies able to comply with the emissions standard at a lower cost. This improves cost-effectiveness, but when one compares such tradable reduction credits to cap-and-trade, then credit trading contains an important inefficiency. Although the emissions standard limits the emissions, the emissions within the limits set by the emissions standard remain without a price (Nentjes and Woerdman 2012). When selling credits, the received amount of money is equal to the sum paid by companies that exceed the emissions standard to purchase the credits. Consequently, for the group of companies as a whole, the cost of the permitted emissions is nil. Pollution not exceeding the relative standard is for free, and absolute emissions are allowed to rise if production or energy consumption increases.

As a consequence, there is no incentive in a performance standard rate trading system to reduce emissions by economizing on fuel input or by slowing production, because this does not earn emission reduction credits. Such credits can only be earned through reducing emissions per unit of energy or output. Mandated emissions released in producing the good have no price, and therefore, their costs are not included in the price of the product. The price of the product is then too low, which leads to overconsumption. The wider range of reduction possibilities in a cap-and-trade system leads to lower total emission reduction costs than in a performance standard rate trading system (Deweese 2001; de Vries et al. 2013).

An alternative, perhaps more simple way of explaining the difference in efficiency properties between cap-and-trade and credit trading is by looking at the supply and demand of emission rights (Woerdman 2004). If the economy grows in a cap-and-trade scheme, the demand for allowances increases, but the supply of allowances remains constant as a result of the emission ceiling. The emissions target will be achieved, and the emissions scarcity is reflected in a higher price for carbon-intensive products. If the economy grows in a credit trading scheme, however, not just demand but also supply of credits will increase since companies do not have an emission ceiling but have to observe an emissions standard. If an energy-intensive company wants to expand production, or if a newcomer enters the industry, it thus has a right to new emissions. The consequence is that the social costs of the extra emissions are not fully reflected in the costs per unit of product. Carbon-intensive products are therefore priced too cheaply.

Project-based credit trading improves the cost-effectiveness of reaching the emissions targets of the investor, but certainly does not have the full-blown efficiency properties of cap-and-trade where each unit of emissions has a price. The project-based variant of trading emissions also suffers from relatively high transaction costs, such as information costs, contract costs, and enforcement costs. Projects such as those under the JI or CDM framework usually require

pre-approval to check the environmental integrity of the project baseline, thereby raising transaction costs. Baseline standardization could improve this, by means of developing business-as-usual scenarios for several project types and regions, so that it will not be necessary anymore to construct a baseline for each individual project.

Acceptance

In order to be implemented, an emissions trading scheme needs to be politically acceptable. If an emissions trading scheme is not accepted by a political majority (or by a powerful minority), there will be no emissions trading scheme in the first place.

With respect to acceptance, the emissions trading literature has mainly focused on acceptance by companies (Dijkstra 1999). Performance standard rate trading produces cost savings for both buyers and sellers. The introduction of these credits, to supplement an emissions standard, is therefore likely to receive broad support from companies. The sale by auction of emission rights under an emissions cap is likely to be less acceptable for companies, in particular for those firms that compete on an international product market (Grubb and Neuhoff 2006). Allocating allowances for free basically has the same efficiency properties as selling the allowances at auction (Hahn and Stavins 2011).

Established companies that grow relatively fast are aware that they will not be permitted to produce higher emissions under a cap-and-trade scheme as they expand their production capacity. For this reason, they do not only prefer free rights above sale by auction, but they would rather opt for performance standard rate trading. However, companies that are able to cut emissions more cheaply prefer cap-and-trade because the demand for emissions in this system is higher than in a credit trading scheme.

There is some literature that has also focused on acceptance by politicians (Woerdman 2004). Despite the efficiency advantages of allowance trading, politicians are usually still somewhat inclined to opt for credit trading. A political economy explanation is that credit trading has advantages for certain interest groups, such as the

energy-intensive industries which do not have to purchase extra emission rights if they want to expand their production. However, there are also some advantages of credit trading for politicians themselves. Allowance trading sets emission ceilings via a rather “complex” process of allocating environmental property rights, whereas credit trading more “simply” uses existing environmental policy to calculate the tradable emission reductions. The “political transaction costs” (or start-up costs) of allowance trading are relatively high since it comes to replace existing environmental policy, while credit trading builds increasingly on extant policy, ineffective and inefficient as it may be. Moreover, under allowance trading, a choice must be made between auctioning allowances or giving them away for free, whereas emissions are always handed out for free under credit trading.

The acceptance of project-based emissions trading depends on a number of things, including the political desirability of an emissions cap, the monitoring and enforcement capacities of the administrative infrastructure, and the political merit of using market-based instruments in the first place. Countries that do not want to impose an emissions cap on their industries now, for instance, because they do not want to restrain economic growth in order to fight poverty, will not implement a cap-and-trade scheme. They are also likely to prefer project-based emissions trading to performance standard rate trading, the latter of which is more systematic in approach and thus more demanding in terms of administrative infrastructure. Governments that are critical of neoliberal market approaches are less likely to adopt any of those emissions trading design variants, although their views could change if they discover that they can earn money from selling emission rights. This attitude change has been witnessed for many poor developing countries in the case of the CDM under the Kyoto Protocol, for instance, in Africa. Being opposed first to rich countries “buying their way out” of their reduction obligations, poor African countries actually wanted to attract more CDM projects later, as soon as it became clear to them that such projects are lucrative and that most projects were going to countries like China where transaction costs are lower.

Emissions Trading Hybrids: The Case of the EU ETS

The European Union Emissions Trading Scheme (EU ETS) is a hybrid of the emissions trading design variants discussed above (Nentjes and Woerdman 2012). This regional carbon market has been up and running since 2005 and targets the power sector, a number of industrial sectors, and the aviation sector. It covers 30 countries in Europe and caps about 40% of their greenhouse gas emissions. The EU ETS has a number of implementation problems (e.g., Faure and Peeters 2008; Jaraitė et al. 2013; de Perthuis and Trotignon 2013; van Zeven 2014), for which there is not enough space here to treat them at length (for a recent overview and analysis, see Woerdman 2015). One of the causes of those implementation problems (but certainly not the only one) is that the EU ETS is a hybrid in at least two ways:

- By combining cap-and-trade with elements of performance standard rate trading
- By allowing a limited import of credits generated from CDM projects

The first hybrid element of the EU ETS concerns its new entrant and closure provisions, which resemble those of a performance standard rate trading scheme. In the textbook model of cap-and-trade, new and growing firms have to buy allowances from established companies or from a government reserve. The EU ETS, however, allocates allowances free of charge to newcomers as well as to industries expanding their production capacity (in excess of 10%). This is primarily the result of industry lobbying. Moreover, in the textbook model of cap-and-trade, a company closing down a plant can sell the allowances that remain. In the EU ETS, however, allowances need to be surrendered in case of installation closure or in case of significant decline in production capacity. This was mainly desired by politicians considering it unfair if firms would keep their allowances in such cases. Unfortunately, these credit-like rules lead to the following inefficiencies (e.g., Ellerman 2007; Nentjes and Woerdman 2012).

If companies would keep their allowances in case of closure, it would be more attractive to shut down old, inefficient plants since the allowances could then be sold. Since a company loses its allowances under the EU ETS, however, the closure of dated, climate-unfriendly installations is made less attractive, which is inefficient. Moreover, if (variable) production costs cannot be covered anymore, a company would normally shut down its installations and leave the market. Since a company will lose its allowances under the EU ETS, however, an incentive is provided to companies that make losses to maintain production capacity in order to continue receiving free allowances which can then be sold. Maintaining capacity which is not deployed for production purposes is inefficient. In addition, when newcomers or expanding firms make calculations preceding their capacity investment decision, they do not have to take the market value of their allowances into account because they get them for free. No opportunity costs are attached to this because allowances are surrendered in the event of plant closure or decline in production capacity. Here the allowances allocated for free act as credits when deciding on production capacity, like in a system of performance standard rate trading. Carbon therefore remains unpriced when production capacity is expanded, which is inefficient.

The second hybrid element of the EU ETS concerns its possibility to import relatively cheap credits generated from CDM projects to further enhance cost-effectiveness. CDM credits can be traded for EU allowances. To safeguard the effectiveness of the scheme, however, the import of CDM credits is quantitatively restricted for companies (to 11% of their allocation in the period 2008–2012 or, for newcomers, to 4.5% of their verified emissions during the period 2013–2020). The reason for this quantitative restriction is twofold: the import of such credits increases the overall emissions cap and the environmental integrity of project-based credits may be weaker than that of allowances in a cap-and-trade system. There are also qualitative restrictions as CDM credits are not allowed to be imported from nuclear energy projects, reforestation activities, or projects involving the destruction of industrial gases.

Summary

Emissions trading is a market-based instrument to achieve environmental targets in a cost-effective way by allowing legal entities to buy and sell emission rights. There are three basic design variants of emissions trading: cap-and-trade (allowance trading), performance standard rate trading (credit trading), and project-based credit trading (such as domestic offsets, JI, and the CDM). In practice, emissions trading schemes can be hybrids of these design variants.

Cap-and-trade is effective in reducing absolute emission levels because it operates under an absolute emissions cap. Cap-and-trade is also efficient, since each unit of emissions has a price. When emissions start to rise in a performance standard rate trading scheme, however, an absolute emission level can only be achieved if the emissions standard is strengthened. An inefficiency of performance standard rate trading is that not every unit of emissions has a price. Moreover, as opposed to cap-and-trade, there is no incentive to reduce emissions by economizing on fuel input or by slowing production. Project-based credit trading is less systematic and more ad hoc due to its project focus. This also entails relatively high transaction costs, although standardizing baselines for several project types and regions helps to reduce those costs.

Firms will generally lobby in favor of free emission rights based on performance standard rate trading. Various politicians also tend to favor such tradable credits if this builds upon already existing direct regulation. As a result, emissions trading schemes sometimes become inefficient hybrids of the design variants discussed above, such as the EU ETS.

Nevertheless, those politicians that want to reach an absolute emission level at the lowest possible cost favor cap-and-trade. The current international dissemination and intended linking of cap-and-trade schemes underlines the growing relevance of emissions trading. Future research on the design elements and implementation problems of real-life emissions trading schemes could help to improve their effectiveness, efficiency, and acceptance.

Definition

Empirical analysis uses empirical research methods from economics and the social sciences in an attempt to provide answers to research questions in the field of law, i.e., in order to investigate the operative and functional aspects of law and legal consequences. The goal of empirical legal

research is to make a contribution to all subjects and phenomena that are of interest to legal scholars and for which no methods have previously been available. The use of empirical methods in legal science can therefore lead to results that cannot be achieved by traditional law research with the methods at its disposal. The ultimate aim of the approach is to contribute to a systematic understanding of our legal system based on empirical data.

In empirical analysis research methods from the social sciences are used to examine research questions in the legal sciences in order to study the operative and functional aspects of the law and their effects (Baldwin and Davis 2003, p. 880). The increasing trend toward testing hypotheses and questions has been described as “the next big thing” in legal science (George 2005, p. 142), even as a revolution (Ho and Kramer 2013) whose significance has as yet been underestimated (Gordon 1993, p. 2085).

In the USA the research approaches of the social sciences first began to take on greater significance in connection with legal realism. Legal realism grew up in the 1930s and 1940s, mainly in the USA, and was characterized especially by the use of interdisciplinary methods borrowed from the social sciences (Eisenberg 2011, p. 1720). In legal realism it was, for example, assumed that judges’ decisions were determined not only by laws, precedents, and general legal principles but also by the judges’ social backgrounds and political convictions (Baldwin and Davis 2003, p. 882). For example, social scientific methods were needed to be able to analyze judges’ verdicts from this viewpoint. Since these methods are often empirical, legal realism introduced the empirical paradigm into the legal sciences for the first time. However, these early empirical research efforts remained few and far between, and thus legal realism fell short of its empirical potential. Because legal realism brought the empirical approaches into the legal sciences and thus prepared a basis for their acceptance, it is seen as the trailblazer of empirical research in the legal sciences (George 2005, pp. 144–145).

Since the beginning of this century, the main country in which empirical legal research has

been practiced to any great extent is the USA (George 2005, pp. 141–142). Today it has a wide forum (Eisenberg 2011, pp. 1713–1714) in a number of journals with international repute (e.g., the *Journal of Empirical Legal Studies*, the *Journal of Legal Studies*, the *Journal of Law and Economics*, and the *European Journal of Law and Economics*), at conferences (e.g., the Annual Conference on Empirical Legal Studies and the Annual Conference of the European Association of Law and Economics), academic societies (e.g., the Society for Empirical Legal Studies, the American Law and Economics Association, the European Association of Law and Economics), and university research centers (e.g., the University of California at Berkeley – Center for the Study of Law and Society; University of California, Los Angeles – School of Law Empirical Research Group; and Hamburg University – Institute of Law and Economics, Germany). It appears likely that its initial rapid growth will continue in the future. The success of empirical methods in the legal sciences is partially due to the fact that it brings together scholars from several different disciplines who have been working independently of each other on different aspects of the legal system, e.g., the sociology of law (“Law and Society”) and the economic analysis of law (“Law and Economics”). This promotes interdisciplinary legal research (Eisenberg 2011, pp. 1719–1720 and 1722–1724).

The common goal of these different disciplines is to develop a systematic understanding of the legal system based on empirical data (Eisenberg 2011, p. 1720). The issues covered by this research are broad. The main focus is on analyzing how legislators enact and implement legal regulations and how these regulations affect the behavior of those to whom they are applied (Ulen 2008, p. 74). Empirical legal research strives as far as possible to make a contribution to all issues and phenomena which, while they are of importance for lawyers, have not previously been empirically investigable because of the lack of methods (Suchman 2006, p. 2).

The development of empirical legal research as an independent field of legal science is sometimes seen as a response to the fact that traditional

scholars of legal doctrine neglected to do empirical research on the actual functioning of the legal system (Eisenberg 2011, pp. 1734–1735). On this view, as a result of the lack of empirical data on our legal systems, many of the theories, assumptions, and prognoses on which traditional legal research has been based, either implicitly or explicitly (Ho and Kramer 2013, p. 1202), have been left without empirical support and therefore remain vague. Moreover, as a result of this neglect, the actors involved in the legal system such as the courts, parties to actions, lawyers, political decision-makers, and society in general are only insufficiently informed about the functional aspects of the legal system (Eisenberg 2011, pp. 1736–1737). Empirical legal research can be seen as an attempt to remedy this state of affairs.

The Contribution of Empirical Analysis to Legal Science

The use of empirical methods in the legal sciences can lead to insights that traditional legal research is unable to achieve with its methods. In this section the limitations of empirical research will be discussed. For reasons of space only a few central aspects will be highlighted.

Objectivity and Value Freedom

Economists and empiricists working in the legal sciences frequently adopt the view, which originated in the natural sciences, that empirical research is objective and can thus be value-free (Friedman 1953, p. 3; see also Sen 1981). However, it is highly doubtful whether it is really possible in the context of economics and the social sciences to explain, analyze, and interpret data in a value-free way. If we assume that it is not possible, this empiricist view reduces the value of empirical research for institutions, decision-makers, and politics (Hausman and McPherson 2006). This may also apply to the legal sciences since this view may result in a neglect of moral and ethical issues. Empirical research data would then be of little use to legal scholars (Hausman and McPherson 2006, pp. 291–308). Thus the support provided by empirical research for finding

solutions to normative issues, which requires a weighing up of philosophical and ethical arguments, is limited (Lawless et al. 2010, p. 21).

Qualitative and Quantitative Research Approaches

Since empirical legal science is mainly US based, it uses almost exclusively quantitative research methods, i.e., methods which are used to analyze statistical data (Suchman 2006, p. 2; Chambliss 2008, pp. 25–26). To date qualitative research methods, which are widespread in the social sciences in Europe and are employed to evaluate data from sources such as texts and audio and video and other forms of visual material, have not played such an important role (Baldwin and Davis 2003, pp. 891–892). One reason for this neglect is that in the USA empirical legal science is closely allied to the economic analysis of law (“Law and Economics”). This movement originated in economics which, unlike other social sciences, does not use qualitative research methods on principle, since they are seen as being too “soft,” i.e., not sufficiently objective. Since in Europe the sociology of law has traditionally played an important role, its quantitative orientation may have constituted an additional barrier to the spread of empirical analysis in Europe (Posner 1997, pp. 5–6).

Methodological Problems and Oversimplification of the Complexity of Legal Issues

Like all interdisciplinary research approaches, research in empirical legal science requires a high level of specialized knowledge of the various scientific disciplines. The fact that legal scholars need to acquire the methodological know-how of the social sciences (Eisenberg 2011, pp. 1728–1729) and social scientists, the detailed knowledge that legal scholars have of the functioning of the legal system (Baldwin and Davis 2003, p. 883) results in two main problems for empirical analysis. These are the methodological problems of empirical research and the problem of reducing legal complexity. Both problem areas are briefly described below.

Methodologically, empirical legal science is criticized for being of lower-than-average quality, although it can be doubted whether the standards of other forms of (interdisciplinary) research are actually any higher. The reasons for such methodological problems vary. They frequently arise from the incorrect use of methods adopted from the social sciences or from flawed research designs. In order to counteract these problems, empirical legal science needs to develop its own methodological discourse. In the long term this could promote a sustainable awareness of methods and thus improve the quality of empirical analysis (Eisenberg 2011, pp. 1730–1731). Some of the traditional publications of legal science, e.g., in the USA the student-edited law journals and in Europe-edited volumes, may not really be suitable for ensuring the methodological quality of the empirical studies submitted for publication (Chambliss 2008, pp. 26–28).

Another criticism frequently leveled at the empirical legal approach is that they reduce the complexity of legal issues (Baldwin and Davis 2003, p. 883). Such reduction is foreign to classical legal scholars, since it is not required for their traditional methods. However, if the behavior of relevance to law is to be investigated with sufficient methodological rigor in empirical studies, it is often unavoidable. Thus the decision as to what extent basic legal conditions should be taken into account in an empirical study is of substantial importance. If the legal facts are oversimplified in the interests of methodological stringency, the results of such research can have little relevance for legal science. In order to avoid this, it is necessary first to present the legal issue to be examined in its full complexity. Only then can the complexity be reduced as required. Care must be taken to fully inform the recipient of the research results of this reduction (Faust 2006, pp. 849–850). If the complexity is reduced in accordance with these requirements, this usually satisfies the demands of legal science, particularly since it is rare for the results of empirical research to replace legal discourse; as a rule they merely provide an additional perspective.

Finally, it is important to be aware that there are areas of legal science in which such reductions in complexity are not possible and which cannot

therefore be investigated by means of quantifying methods. Even technically well-implemented empirical projects must fail when their subject matter is of an ethical and moral nature. Here it can be perturbing if issues that cannot be quantified are more or less uncritically functionalized. It is the task of discourse in legal science to critically assess the value of such research.

Future Directions

In continental Europe empirical legal research is currently less widespread than in the English-speaking countries, and many obstacles to its gaining more acceptance still need to be overcome. Legal scholars who have no basic knowledge of the empirical research methods required may initially find it disturbing that the utility and scope of such research efforts in the legal sciences have often not been sufficiently clearly defined (Hull 1989, p. 915). Moreover, since it is often seen as being closely linked to economics, legal scholars sometimes think that empirical legal science is theoretical and abstract, naively functionalist, or politically conservative. Today these preconceptions can no longer be considered justified (Klerman 2002, p. 1167). Empirical analysis can contribute to a systematic, empirically based understanding of our legal system. It can therefore be assumed that it will play an increasing role in the future, not only in the English-speaking countries but also in continental Europe and other non-English-speaking countries.

Definition

Evidence shows that, contrary to what believed traditional legal theorists, judges when making decisions are not merely making a pure exercise of interpretation of the law. They are influenced by factors such as panel composition, material and nonmaterial benefits, pressure groups, etc., and may follow distinct trends. This chapter presents some models that explain judicial behavior or judicial decisions. Recent (and not so recent) empirical literature has been providing a rich debate in this still recent discussion.

Introduction: Why Care? Judicial Outcomes and Economic Performance

If judges have a substantial amount of discretion in deciding cases, then it is important to know the motives and the value systems which influence their exercise of discretion. (C. Hermann Pritchett 1968)

Coase (1960) taught us that courts and court outcomes – i.e., judicial decisions – impact the economy. Several other authors have also shown empirically that while well-functioning courts provide proper environment for productive activities, guarantee contract enforcement, and reduce uncertainties in the economy, malfunctioning courts may deter growth, investments, job creation, and increase insecurity (e.g., Weder 1995; Sherwood 2004). Since judicial decisions are courts’ main “product,” evaluating “how judges judge” and “what explains judges’ decision making” becomes a crucial task.

Although this is a complex job, which has recently been aided by studies in fields such as cognitive sciences and empirical psychology, scholars of different backgrounds (political sciences, law, economics, sociology, etc.) have been debating about this topic for several decades. Pritchett (1968) accounts Charles G. Haines as being one of the pioneers in the study of judicial behavior, with the publication of “General Observations on the Effects of Personal, Political, and Economic Influences in the Decisions of Judges” in a 1922 edition of the *Illinois Law Review*. Pritchett himself is considered by many, one of the original creators’ of this field (Epstein 2016).

From the View of Judicial Decisions as Pure Interpretations of Law to Richard Posner's Nine Theories of Judicial Behavior

One frequent concern among judicial behavior scholars is whether judges are influenced by their preconceptions or ideologies. A long debate over this issue – and not yet finished – puts *legalists* in one side and *realists* in the other. Adepts of legalism would argue that when judges judge, they are purely interpreting the law, in the best manner they can; therefore, bringing law into life is the main judicial job. Realists, on the other hand, do not believe there is a unique and certain manner to interpret the law. Each judge, when deciding, is unavoidably influenced by prior beliefs, prior personal and/or professional experiences – even if they try to strictly follow legal rules. This all may be called one's *ideology*. Realist scholars then are mainly interested in creating good and accurate measures of judges' ideology.

Adept of the realist view of judicial behavior, Posner (2008) would explain judges' personal attitudes in terms of "Bayesian preferences," as defined by Bayes statistical theorem: it shows that future probabilities of a certain kind of behavior – or decision – may be explained by former probabilities of that same behavior. Thus, in order to predict the occurrence of a certain type of behavior/decision by a judge, researchers should evaluate how was his/her decision in the past.

Besides that, Posner summarized and further developed years of theorization in judicial behavior. The author categorized nine theories of judicial behavior: Attitudinal, Strategic, Sociological, Psychological, Economic, Organizational, Pragmatic, Phenomenological, and Legalist.

Attitudinal: The attitudinal theory explains that judges' decisions are mainly reflections of their political preferences or what it is called political ideology.

Strategic: The strategic theory argues that judges' decisions reflect their preoccupations with external factors, such as opinions and pressures coming from peers, other political powers, and the rest of society (public opinion, media, interest groups, etc.).

Sociological: This theory is focused on smaller judging groups and explains why factors such as panel and voting compositions do affect judicial decision.

Psychological: The psychological theory focuses on explaining how one's preconceptions influence decision-making in circumstances under uncertainty. As Posner poses, legal systems, especially (but not only) the one in the USA, is fundamentally characterized by uncertain events, facts, and information.

Economic: The economic theory presents judges as rational, utility maximizers, who constantly behave in response to incentives and constraints. In this case, utility maximizing may be related to desire for leisure, promotion, good reputation, or even, internal feeling of satisfaction. Thus, the economic model may also encompass the strategic and the sociological theories of judicial behavior.

Organizational: The so-called agent-principal problem is the basis of the organizational theory. Mainly, this model considers judges as agents of a principal (the government) and seeks to explain judicial decisions under this perspective.

Pragmatic: The pragmatic model explains that judges are concerned with and do consider the consequences of their decisions. It is also known as the *consequentialism* approach of judicial decision-making.

Phenomenological: Posner explains that "phenomenology studies first-person consciousness – experience as it presents itself to the conscious mind" (p. 40), so this theory relates to the self-consciousness of judges when judging.

Legalist: As briefly explained above, legalism views judicial decision-making as a "pure" interpretation of the law. Legalists believe that judges when deciding at courts are solely impacted by their effort to apply the law, not being disturbed by other influences, especially, any personal preferences or preconceptions of any kind.

Due to the complexity of the phenomenon of judicial decision-making, Posner recognizes that there is no single theory able to explain it entirely. Therefore, the theories above are, actually, complementary and not substitutes.

This entry adopts some of these perspectives (e.g., attitudinal, economic) and less others (e.g., phenomenological, legalist). In subsequent sections, we provide references for empirical evidence corroborating some of these theories, especially the Attitudinal, the Strategic, and the Sociological.

Common Law Versus Civil Law: Unified or Different Models for Judicial Decision?

Early literature on judicial decisions was based on common law systems, as it happened with most of the literature on economic analysis of law. Yet, the analysis of judicial decisions has no absolute boundaries across different legal systems. The reason is simple. Judges judge lawsuits, no matter where, or under which system. In modern days, even common law judges follow constitutions and statutes, and civil law judges, not rarely, adhere to precedents (some instances in mandatory, or quasi-mandatory manner – as lower court judges following higher courts – and some other instances voluntarily). As Schneider (2005) poses, it is unreasonable to believe, as orthodox legal theory assumes, that civil-law courts only apply the law coming from the legislature. Because of that, “propositions asserting substantial differences between common-law and civil-law systems may be overstated” (p. 139).

Thus, one can infer that judicial decision-making may be analyzed as one single phenomenon, independently of the locus where it happens. This does not mean that one might not eventually find out that the outcomes of judicial decisions differ from one country to another or from one system to the other. It may also be possible to find out that judges do have different tendencies in their judicial making depending on where they are. For instances, one might conclude that judges in some countries tend to be more sensitive to “social issues,” such as inequality and wealth distribution and that their decisions reflect these concerns. Yet, these results are related to the *different variables affecting the process of judicial decision*; it does not mean that there are different

models of judicial decision, one for each legal system. It is also not true that judges, when faced to similar incentives or constraints, behave differently according to their legal origin. As the literature shows, different modes of judicial behavior are caused by different constraints and incentives which judges are faced to. The different models used to explain judicial behavior, as proposed by Posner’s “Nine Theories of Judicial Behavior,” described above, illustrate this idea.

Some Early Literature on Judicial Behavior and Decision-Making

Focusing on the US Supreme Court, and beginning in 1940s, Pritchett developed several empirical methodologies for the analysis of judicial behavior, among them, “bloc analysis” and “attitude analysis.” While later the author himself considered the first one “a rather primitive device” (1968, p. 499), it was a very useful tool for the evaluation of Justices’ voting patterns in non-unanimous decisions. Based on observations for more than 20 years, Pritchett found evidence of persistent divergences between Justices based on ideological differences. Along with “bloc analysis,” the author employed “attitude analysis.” It was one of the first attempts ever in the literature to include personal characteristics – or “personal policy attitudes” – as determinants of stronger than average voting patterns by the Justices. Pritchett’ main hypothesis was that judges are influenced by their personal ideologies, and their decisions at courts are not mere interpretations of the “letters of the law.” This methodology, which employed a “box score” to register Justices’ attitude, became a classical reference in the literature of empirical analysis of judicial decisions.

Tate (1983) created a compendium of different methodologies applied in different studies. His analysis encompassed qualitative and quantitative approaches and was complemented with critical comments. At that time, the author showed optimism in the potentials of “standard statistical methods such as regression analysis” for the study of judicial behavior (p. 74).

Fon and Parisi (2006) developed a dynamic theoretical model to explain judicial decision making in civil law systems. Their focus was not on judges as individuals, but on the result of their action, i.e., decisions and precedents. The authors evaluated the circumstances under which legal rules may be consolidated or may be corroded at courts. In their model, external shocks usually push the system into a dynamic trend, pulling it away *or* towards the point of consolidation of rules. In turn, institutional threshold of *jurisprudence constante* played a crucial role in the definition of this dynamic path.

Factors Impacting Judicial Decision: Empirical Evidence

Several factors may affect judicial decision, besides the manner by which judges interpret the law (as legalists would argue). Those would include internal factors (such as one's ideology) and external factors (such as pressures from public opinion); some may change throughout one's career (again, ideology would be an example, though here we are speaking of ideology in a broad sense), and others are constant for a certain individual (such as gender or race). The outcome – i.e., how judges effectively judge – is a combination of all those factors, and no single one explains it all, all the time. For this reason, empirically measuring the impact of a certain factor is not an easy task. Luckily, much has been advanced in the last decades. Let us review some literature on these.

Ideology

“How much ideology affect judicial decisions” is one of the most common themes in empirical analysis of judicial behavior. Since the 1st half of the twentieth century, Pritchett succeeded in finding evidence that US Supreme Court Justices were influenced by political ideologies when judging (as before). This is what Posner called “the attitudinal theory,” which “deploys... highly developed apparatus to determine the extent to which actual judicial decisions reflect the attitudes or ‘ideology’ of the judge rather than the

dictates of the ‘law’” (Cameron and Kornhauser 2017, p. 536).

As proponents of this theory, Epstein, Landes, and Posner (ELP 2013) point to the fact that there are *ex ante* and *ex post* measures of judges' political ideology. For Supreme Court Justices, the most common *ex ante* measure is the party of the nominating President. But since nominations must be approved by the Senate (and this is true for many countries), some scholars have also used measures of senatorial influence to capture Justices' ideology. Others have used editorials of influential newspaper to capture US Supreme Court nominees' *ex ante* ideological profile. *Ex post* measures, as one would expect, are based on evaluations of Justices' and judges' votes, speeches, and articles. Researchers usually combine qualitative and quantitative analysis of written and oral material produced to infer one's ideological inclinations. ELP (2013) show that “judicial self-restraint [on personal ideology] has long been in decline [since the 1960s]” for US Supreme Court Justices. In other words, the impact of ideology has been growing over time. For other courts in the USA, the authors indicate that ideology also plays a role, although in weaker magnitudes. This means that ideology has proportionally more influence at the top of the judicial hierarchy (Cameron and Kornhauser 2017).

Supreme Courts outside the USA seem also to be influenced by ideology in their judicial decisions. Yeung and Azevedo (2015) use a set of approximately 1700 decisions of the STJ (Superior Tribunal de Justiça), one of the two supreme courts in Brazil (being STJ decisions eventually appealable to STF, the Federal Supreme Court). Their original objective was to evaluate whether this court tended to favor small debtors in contractual disputes involving financial institutions. There is widespread anecdotal evidence that Brazilian courts favor weaker parties and disfavor banks. As an overall result, the authors did not confirm this popular belief. Yet, when analyzing specific variables, evidence of ideological decision emerges. For instances, Justices at the STJ decide differently depending on who stands as the defendant party: if an individual appear as defendant, the debtor tend to be favored

in a significant manner, as compared to the instances in which an enterprise appear as defendant. Justices seems to believe that, faced with financial institutions, individuals need more protection by the law than enterprises do.

Another evidence of ideology was assessed indirectly in this study. Being an appellate supreme court, STJ receives cases from 2nd degree state courts from all over the country. The authors measured whether there was any “regional factor” affecting STJ decisions. The only state with a significant result was the Brazilian southernmost state, Rio Grande do Sul: cases with that origin were consistently reformed by the STJ Justices, and in the direction of *disfavoring* debtors. It was clear that they used their power to “correct” some pro debtor trend by the Southern judges. Curiously, there is a long lasting theoretical discussion behind this fact: historically, the state of Rio Grande do Sul has been known as the birthplace of a judicial movement called *Associação dos Juizes para a Democracia* (“Association of Judges for Democracy”), whose main goal is to promote “social justice,” or more precisely, wealth redistribution, by means of the Judiciary. Judges from that state are known to be adepts to this movement and, for this reason, to be more sympathetic to “social issues,” and less favorable to the “big capital,” as banks and big enterprises. Ideological influences on their decisions are not only undisguised, but in fact, a clear statement. In this sense, Yeung and Azevedo’s results find evidence of two ideological impacts: one by judges in the state of Rio Grande do Sul, which is *pro debtor*, and the other, by the Justices at STJ, overall regarding the southern judges as “biased.” Both results were consistent and statistically significant.

Further effects have been observed in Justices’ ideologic profiles. ELP (2013) distinguish two phenomena: the *ideological drift*, and the *ideological divergence*. The former captures changes in a Justice’s *ex ante* ideology since his/her appointment to the Supreme Court. The second refers to changes in the Justice’s ideology compared to the ideology of the nominating President. This effect explains why Justices may, sometimes, vote different to what is expected. Ideological divergence

may happen gradually (i.e., Justices start at the Supreme Court much aligned with their nominating President, but then divergence increase due throughout the time), or it may exist since the beginning of a nominee’s career at the Supreme Court. In this case, it may be caused by the President’s lack of information about the nominee’s profile, or it may happen because the President had other political compromises when nominating the Justice, which were unrelated to ideological positions.

Abundant are theories and empirical evidence of ideology impacts on judicial decision-making; it is not the only factor explaining judges’ behavior. It would be naïve to believe that judges, even Supreme Court Justice, would be able to use their discretionary power to entirely (and only to) pursue their personal ideologies. Several other constraints curtail these motives.

Gender

The impact of a judge’s gender on judicial decision has also been studied in several studies; as before, we bring a short selection.

Peresie (2005) finds judges’ gender as an impacting factor on decisions at USA appellate courts on disputes over sexual harassment and sex discrimination. Gender acts as a direct impact factor – i.e., female judges favor more frequently the victims of discrimination – and as an indirect factor, through peer effect on panels – i.e., female judges do influence their male counterparts when judging such cases. Peresie finds that panels with female judges tend to favor alleged victims twice as often as panels with only male judges. In this study, gender was more impacting than ideology on judicial decisions.

Farhang and Wawro (2004) find a strong panel effect by women, i.e., female judges tend to influence their male colleagues in the panels. Yet, they find that a second woman on the panel does not have the same effect as the first one. These authors also try to find evidence of race impact, but – differently to the gender factor – they find none, although they are cautious to interpret this latest result.

Boyd et al. (2010) employ propensity score matching and also find significant gender impact

in sex discrimination disputes. Here, as in Peresie (2005), impacts occur both directly (on individual female judges) and indirectly (on male counterparts in panels). Although the authors analyzed 13 types of judicial disputes, only those on sex discrimination were significantly impacted by the judges' gender. Within their list of analysis, there were other types of disputes that are usually gender sensitive, such as abortion and sexual harassment, but on no other issue had gender significant impact.

Other studies bring similar evidence for courts outside the USA. King and Greening (2007) analyzed decisions by the International Criminal Tribunal on cases of sexual assault in former Yugoslavia. They found that female judges tend to punish more severely defendants who assaulted women – in what constitutes a “gender solidarity” between judges and victims. This solidarity seems also to be present when all-male panels analyzed cases involving male victims: sentences for these cases were more than 100 months lengthier than those in which there was at least one female judge on the panel. In France, under the context of child support orders, Bourreau-Dubois et al. (2014) find that when the parents' average offer is reasonable, female judges tend to be more generous than male judges.

Grezzana and Ponczek (2012) analyzed more than 90,000 labor disputes at the Brazilian Superior Labor Court. Overall, the authors find no evidence of gender impact. However, once they control for the object of dispute, impact is evident for cases such as “wage equalization” and “employment and union link.” Under these circumstances, female judges tend to favor female litigants (workers), whereas male judges tend to favor male ones. Again, there seem to be some kind of “gender solidarity” between judges and litigants in the Brazilian Superior Labor Court.

Why would judges' gender have impact on the manner by which they decide? Based on previous literature, Boyd et al. (2010) draw 4 accounts affecting judging, either individually or in groups (panels). First, *different voice* is the manifestation of the differences that male and female individuals see and analyze the world and society; basically, this is the individual

perspective of things, particularly here, of the cases disputed at courts. *Representational* account is the manifestation of female judges seeing themselves as representatives of all female individuals in society, and specifically, of female litigants in disputes. Female judges would decide in favor of women in cases where there are particular interests for the whole class of women in society. Third, *informational* account posits female judges as having more information that would be valuable for resolving the dispute. Under such circumstances, their male counterparts would benefit from this privileged information, and the effect will be channeled through the panel voting. Last, *organizational* account will actually oversee the gender impact on judicial decisions; the view here is that professional training and institutional rules in the Judiciary are clear and similar enough to minimize any significant differences between male and female judges. All these accounts have been explored, tested, and analyzed by a rich literature on this topic Boyd et al. (2010) provide detailed references on each of these approaches.

Besides gender, there are other factors affecting judicial decisions, which are related to minority groups such as race, ethnicity, religious group, and social background, among others (e.g., an interesting piece of work by Schwartz and Murchison 2016, on the impacts of ethnicity-nationality at the Constitutional Court of Bosnia-Herzegovina). Due to the limitations of this chapter, we will leave these topics undiscussed, despite their undoubted importance as the empirical literature on judicial behavior has already shown.

Voting Panels, Composition, and “Peer Effect”

Before, we have seen some accounts of how panel composition at courts affect judges' voting patterns. Social psychologists and behaviorists have long studied the effects of peer pressure in organizations, mostly enterprises, and one would expect – and actually observe – the same happening in public and political organizations, such as courts (and the Congress, etc.).

Epstein, Landes, and Posner (ELP 2013) have a theoretical explanation for the occurrence of panel composition effect, and they test it. Panels

may decide unanimously – when there is no dissenting vote – or non-unanimously – when there *is* dissent. ELP explains that there are costs and benefits of dissenting, and not rarely the former supersede the latter. Costs of dissenting include writing the dissenting opinion, disagreeing with colleagues, and reputational costs infringed on the other members of the panel. All these create *dissent aversion* and, consequently, one will avoid disagreeing on minor issues – specifically technical ones – and dissent more frequently will be caused by ideological disagreements, which are more difficult to resolve by discussion and compromise. ELP (2013) show evidence of this effect for the US Supreme Court from years 1953 to 2008. For other lower courts, the authors predict more dissent when an appeal is being reversed (dissenter has ally in the district court), and less dissent in smaller courts of appeals (judges sit together more frequently, making dissent much costlier). The authors also predict that dissent will be inversely proportional to the court's workload, i.e., the busier judges are, the less they will dissent. Historical evidence from the US Supreme Court and the Courts of Appeals corroborates the authors' predictions. ELP also find that the presence of dissent impact on the length of written voting: majority opinions are longer if there is one dissenting member on the panel, and still longer if there is more than one. Apparently, more words are necessary to justify an opinion when it is faced with opposition. Finally, the authors link the frequency of dissent to one's career: federal judges in the USA tend to dissent more during the first half of their active lives.

Voting panels may also *potentialize* some other factors, for instances, political ideology. As observed by Sunstein et al. (2006, *apud* ELP 2013), judges appointed by Republican Presidents decide against affirmative action cases more often than those appointed by Democratic Presidents; yet, the frequency is much higher for full-Republican panels and much lower for full-Democratic ones. For the gender factor, similar peer effect is observed: all-female panels tend to favor female litigants and the opposite for all-male panels on male litigants (as shown above). However, sometimes, panels may *attenuate* or

even *reverse* ideology impact. Studies have found evidence of liberal judges deciding in more conservative manner on panels than they would otherwise do, and the contrary to conservative judges (check on ELP 2013, chapter 2).

Outside the USA, Smyth (2005) studied the pattern of dissent on the Australian High Court. He finds evidence for dissent caused by diverging political ideology, but no evidence of relation between caseload and dissent rate. As to a judges' active career, Smyth finds evidence of *increasing* dissent rate throughout the time, a diverging result to what ELP have shown for the USA.

Related to peer effects, some interesting literature on the influence of social norms on judicial behavior may also be accounted for. Using an analytical approach, Harnay and Marciano (2004) build up a model in which they show that judicial behavior is not entirely a product of individual calculation; instead, it reflects the interactions in a system where judges do care about what other professionals in the community think and do and have desires for certain degree of conformity. In other words, they show evidence that judicial behavior cannot be explained solely by the economic theory from Posner, but also by elements of the strategic theory. This "tendency to conform" to precedents by a particular judge is a result of a cost-benefit analysis: he/she analyzes the expected gains of deviation versus the gains of compliance with the precedents and does that at the private and professional levels. This, according to the authors, explains why judges behave in conformity to precedents under certain circumstances and deviate under others.

External Pressures: Media, Popular Opinion, and Interest Groups

Besides the effect exerted by peers in voting panels as discussed above, there are other sources of external factors that might influence judicial decisions. Media and popular opinion have always restrained, somehow, public agents' behavior; yet, the intensity of this impact has grown exponentially with the modernization of telecommunication technology. In some countries, Supreme Court voting sessions are broadcast live on TV channels. Although average citizens can

rarely comprehend the matters discussed at courts – and especially high courts – due to their complexity and technicality, from times to times Justices' decisions are in the spotlight, highlighted on the front pages of newspapers, in the evening TV shows, and discussed by lay citizens. Thus, even judges who are not directly elected feel, somehow, constrained by what society has to say about the outcomes of their work. As Epstein and Kobyłka (1992) pose: “Most modern Court decisions reflect public opinion. When a clear-cut poll majority or plurality exists, over three-fifths of the Court's decisions reflect the polls. By all arguable evidence the modern Supreme Court appears to reflect public opinion as accurately as other policy makers” (p. 24).

Organized interest groups may also exert considerable impact on judicial decisions; although not new – at least in the North-American context – this is a phenomenon that has grown recently, and that is still not well understood (Epstein and Kobyłka 1992).

Empirical literature on the effects of media, public opinion, and interest groups on judicial decision is also vast and growing. Due to its higher exposure and its greater impact on the rest of society, studies of this kind have mainly focused on supreme courts. Casillas et al. (2011) find significant influence of public opinion on the US Supreme Court decisions and more impacting in nonsalient cases (because in salient cases, there are high stakes in following legalistic considerations and/or personal ideologies). The authors measure the costs that the Supreme Court incurred by ignoring public opinion in nonsalient cases during the period of 1970s to year 2000. Giles et al. (2008) follow the same direction and, even though they are more cautious about the existence of direct impacts of public opinion on Supreme Court outcomes, they do assert that there is evidence of causality on Justices' voting.

Epstein and Martin (2010) also find evidence that Supreme Court decisions are, to a certain degree, aligned with public opinion. Besides the usual explanation that Justices care about their reputation and society's approval, Epstein and Martin argue that the alliance may occur because Justices *are themselves* part of society and of the public. Thus, in this case, they are actually

deciding based on their personal ideologies, and not only as a reflection of external preferences. It would not be easy to empirically separate these two effects, and the authors leave the analysis for future studies.

With regards to interest groups, Collins and Martinek (2010) find evidence of their impact on the probability of success by appellants, but not by appellees, on the US courts of appeals. For the Supreme Court, Collins and Solowiej (2007) also show that interest groups, represented by *amici curiae* briefs presented to the Court, do affect the amount of information that would be important for judges' decisions. A positive outcome the authors find at the US Supreme Court is that it is accessible to a wide variety of interest groups, which reflect a democratic and pluralistic society. However, despite their clear influence, at least on provision of information, the authors were not able to explain how and how much do these groups affect judicial decision-making.

A notable remark about the involvement of interest groups in judicial decisions is made by Epstein and Kobyłka (1992). They differentiate this type of activity with those of other political pressure groups: “Unlike the more traditional arenas of group lobbying, . . . [the import of interest groups in the Judiciary] is not so much derived from their numbers but is more a function of the kinds of arguments they present to a Court” (p. 306). These authors believe this the manner by which they influence judges' decision.

Pressure coming from the Executive and the Legislature Powers (i.e., the Congress) also exerts significant impacts on judicial decisions. The interplay between judges and those actors has long been discussed by legal scholars and is a never-ending object of study. Especially in the case of Supreme Courts, due to the Presidential nomination of its Justices, the quest for a better understanding of this relationship is related to the crucial matter of independence of powers.

Lopes and Azevedo (2017) find evidence in this direction for Brazil. Under that system, there are two high courts: STJ (Superior Tribunal de Justiça) – for civil appeals – and STF (Supremo Tribunal Federal) – a constitutional court, which is de facto above STJ. Although Justices at both

courts are formally nominated by the President, STF is more political, with closer links to the Executive and Legislative. Presidents also have more discretion in the nomination of STF Justices. Perhaps because of that, this study finds that STF is significantly more impacted by political influences than STJ.

Garoupa et al. (2013) try to understand these influences at the Spanish Constitutional Court. They conclude that, due to the limitations imposed by civil law systems, impacts in this Court do not strictly follow the patterns predicted by the attitudinal model, specifically on the dichotomy liberal x conservative, or left x right.

As of the relations between courts (especially the Supreme Court) and Congress, Epstein and Kobylka pose that “[they] are hardly random. The political composition of the legislature vis-à-vis that of the Court plays a major role in determining the course of those relations, be they antagonistic or amiable” (p. 24). The fact that Supreme Court Justices must be approved by the Senate also poses a constraint to the first. Yet, since policies created by the Congress, if questioned by unsatisfied litigant groups and individuals from society, may be overruled by the Court, the power factor and impact is not a one-way path. Again, due to the limitations of this chapter, we will leave detailed discussions apart. (Further references may be found on Epstein et al. 2013, chapter 2).

Another interesting type of external pressure may affect judicial behavior, specifically at the context of international courts. Under such regimes, in which no strict hierarchy exists between international and local courts, the problem of compliance by these ones is intensified. Dyevre (2016) designs a theoretical model in which he predicts the circumstances under which domestic judges have incentives to accommodate with the European Court of Justice (ECJ). For this purpose, the author employs the concept of *crisis costs*, or costs for domestic noncompliance. The level of these costs is the determinants of the behavior by local judges. His model shows that, in legal regimes as integrated as the EU, non-compliance (or defiance) makes local courts worse off. Because of the magnitude of such

costs, there are incentives for the ECJ and these courts, even strong ones – such as the German Federal Constitutional Court – to seek accommodation through dialogue. For smaller domestic courts, there is no substantial benefit to defy the ECJ generating conflicts. Thus, the extent to which pressure may be exerted upon judicial decision may go beyond national borders.

Indeed, the analysis of international courts, such as the ECJ, renders several possibilities to test hypotheses on judicial behavior. (Other insightful research about judicial decision-making at the ECJ may be found at: Josselin and Marciano 1997; Tridimas and Tridimas 2002; Portuese 2012; among others). In this short chapter, it will not be possible for us to dwell extensively on the multiple works on this theme; yet, we close with one another intriguing work: Vaubel (2009), by analyzing data from 42 countries, shows that the ECJ is indeed biased towards political centralization. Furthermore, and most importantly, this bias is a consequence of independent courts (not the contrary), which are not subordinated to the European Parliament and the European Commission.

Benefit Maximization (or Satisfaction)

Another set of factors that might significantly affect judicial decision-making is the desire that judges have to maximize self-benefits. In Posner’s terms, this is the so-called economic theory of judicial behavior. One example of benefit that judges normally try to maximize is the chances to succeed in their career. By observing the Italian Constitutional Court, Melcarne (2017) corroborates the hypothesis that judges’ career concerns affect their behavior; the reason is the reputational impacts of their conduct. Furthermore, these concerns are independent to judges’ personal characteristics. In line with the discussion in the previous item, Melcarne also observed that judges are sensitive to external pressures, especially interests of the Executive Power.

Schneider (2005) also confirms career incentives in judges’ behavior; yet, his observations of the German Labor Courts go further, by analyzing theories of internal labor markets (or tournaments) in the judicial structure. As a combination of career concerns and external pressures

(as discussed in the previous item), the author shows that “[j]udges are likely to decide in a way that conforms to the policies or opinions of those agencies who influence their appointment. These agencies can be higher-level courts, parliaments, and governments” (p. 140). He also claims that these results might be generalized to other jurisdictions, due to the similarity of the structure of German labor courts and that found in many other civil-law countries.

However, some researchers are cautious about viewing judges as benefits maximizers, whatever benefits might be translated to. As Christmann (2014) poses “[m]odels that treat judges as rational maximizing men commonly find a stronger distortion in the resolution of disputes” (p. 411). Because of this skepticism, and with the influential developments of behavioral economics, a new derivation of the benefit-maximization theory on judicial decision-making is emerging. Authors following this line see judges not as benefit-maximizers, but as Tsoussi and Zervogianni (2010) pose, “satisficers” “who make decisions within real-world constraints, such as imperfect information and uncertainty, cognitive limitations and erroneous information” (p. 333). The concept of “satisficer” comes from Herbert Simon’s notion of “bounded rationality”: instead of fully rational maximizers – who seek the “best” outcome, satisficers make decisions based merely on the choice of “good enough” outcomes. Under this view, judges’ goal “is not optimize but to render opinions that are merely satisfactory” (p. 333), and because of that, they often engage in “improper” behavior, especially under nasty environmental conditions, such as overloaded court dockets and increasingly complex lawsuits.

The theory of judges as satisficers is a promising one, however, still needs to be corroborated by empirical analysis. Hopefully, the ever growing literature on behavioral law and economics will, very soon, bring promising results in this direction.

Above, we have shown several factors that, according to a rich empirical literature, may impact judicial behavior. Due to the limitations of this chapter, the discussion was brief and non-exhaustive. However, some authors argue that

there is still a long way to go, in the study of the factor impacting judicial decision. They claim that several qualitative factors have been entirely left out the discussion up to now. For instances, Richards (2017) points to “background variables, such as [judges’] education, prior experience, training, socio-economic background, personality,” which could “contribute to a more universal understanding of judicial behavior, crossing the boundaries of both space and time” (p. 558). Indeed, much still needs to be done.

Future Directions

What can one infer from this brief discussion and review of the empirical studies on judicial decisions? What have the studies so far evidenced?

At the beginning, the studies had a more *positive* approach: attempts to capture trends in judicial decisions, sources of personal ideology, and other factors that might impact court outcomes.

Throughout the time, as theories and methodologies developed (although, as seen above, there is still much to be pursued), authors of judicial decisions had increasingly (although sometimes not explicitly) adopted a *normative* perspective. Resulting evidence shows that judges are influenced by factors such as panel composition, material and nonmaterial benefits, pressure groups. Based on that, one might ask how institutions should be better designed to provide the “right” incentives for judges to behave in the “desired” manner, by making decisions that are more democratic, more inclusive, more efficient, . . . ? (And each one has his/her own desired outcome for judicial decisions.)

Empirical analysis of judicial decisions has helped to answer these questions, too.

Endowment Effect

Ben Depoorter^{1,2} and Sven Hoeppe²

¹Hastings College of the Law, University of California, San Francisco, CA, USA

²Center for Advanced Studies in Law and Economics (CASLE), Ghent University Law School, Ghent, Belgium

Abstract

A vast body of experimental studies in psychology and economics finds that individuals tend to value goods more and demand higher prices when they own the goods than they would be willing to pay for the good when they do not already own it. Although research on the endowment effect has been done for more than three decades, its theory, empirical methodology, results, and implications continue to be topics of intense discussion among economists, lawyers and psychologists. In this entry, we review the theoretical framework and

empirical evidence on the endowment effect and highlight some implications for law and economics research.

Definition

The term “endowment effect” describes observations of a gap between the willingness-to-pay for a good not owned already and the willingness-to-sell a good in one’s possession. In other words, the term describes the tendency that people value things higher merely because they own them.

Introduction

A major tenet of rational choice theory is that individual preferences are endogenous: although individuals may value things differently, preferences exist independently of situational circumstances. This principle, most commonly referred to as “preference exogeneity” (Korobkin 1998a, p. 611), “source independence” (Issacharoff 1998, p. 1735), and “status irrelevance” (Korobkin 2003, p. 1228), plays a crucial role in the economic analysis of law. For instance, when economists analyze how the legal system should distribute entitlements among competing claimants or how to regulate consensual exchanges of entitlements after their initial allocation, it is generally assumed that legal rules do not influence the value of the entitlement itself.

Behavioral research demonstrates however that the assumption of preference exogeneity does not hold in many circumstances. A vast body of experimental studies in psychology and economics finds that individuals tend to value goods more and demand higher prices when they own the goods than they would be willing to pay for the good when they do not already own it (compare literature reviews and extensive references in: Horowitz and McConnell 2002; Korobkin 2003; Morewedge et al. 2009). The observed gap between the willingness-to-pay (WTP) for a good not owned already, on the one hand, and the willingness-to-sell (WTS) a good in one’s possession, on the other hand, was termed

“the endowment effect” in a seminal paper by Richard Thaler (1980, p. 44).

Although research on the endowment effect has been done for more than three decades, its theory, empirical methodology, results, and implications continue to be the topics of intense discussion among economists, lawyers, and psychologists (cf. Plott and Zeiler 2005, 2007, 2011; Arlen and Talley 2008; Isoni et al. 2011; Klass and Zeiler 2013). This entry briefly reviews the theoretical framework and empirical evidence on the endowment effect. Moreover, it highlights a few implications for the economic analysis of law.

Empirical Evidence on the Endowment Effect

Early demonstrations of the endowment effect at work led to most striking results. In their pioneering study, Knetsch and Sinden (1984) randomly divided experimental participants into two groups. One group received a lottery ticket for a \$50 cash prize. Participants in the other group received \$3 in cash. Then the researchers offered to sell or buy the lottery tickets for \$3. A striking majority of the ticket holders, specifically 82%, kept their lottery tickets. This suggests that the WTA of these subjects was greater than \$3. Moreover, only 38% of the cash owners chose to buy tickets, which suggests a WTP of less than \$3.

In another early study that received much attention, Knetsch (1989) endowed some participants with coffee mugs and later offered each of these participants to trade a large Swiss chocolate bar for a mug. Other participants received a large Swiss chocolate bar and later had the chance to trade the chocolate for one of the same mugs. Surprisingly, not only did merely 11% of the mug owners choose to trade them for the chocolate bar. This would be intuitive if the mugs had a higher value. However, also merely 10% of the other participants, who were endowed with the chocolate bar, were willing to trade it in for a mug. In fact, Knetsch (1989) used a third group to provide a baseline measure. Participants in this group had a choice between a mug and a chocolate bar without any initial endowment. The results

suggest that participants perceived the two goods as roughly equivalent on average: 56% chose the mug and 44% opted for the chocolate bar.

While the endowment effect appears to be robust across ages – at least across ages 5 (children in kindergarten) to 20 (college students) (Harbaugh et al. 2001) – the endowment effect varies across different *types of entitlements*. Due to the constraints of the experimental method, endowment effects are mostly observed for small and tangible consumer items [see, however, a study by Dubourg et al. (1994) on endowment effects for small changes in safety features in the purchase of cars]. Meanwhile, no endowment effects appear to occur when involving tokens with a certain value (van Dijk and van Knippenberg 1996). Conversely, this study observed a significant WTA/WTP disparity when the value of the token was uncertain. In line with this finding, the endowment effect is observed to be more pronounced when it is difficult for individuals to compare the two commodities involved (Bar-Hillel and Neter 1996; van Dijk and van Knippenberg 1998). In a similar vein, Shogren et al. (1994) found that the endowment effect is stronger for endowments for which no close substitutes are available. Curiously, endowment effects were absent in experiments involving items with close substitutes (candy bars), although endowment effects appear robust when concerning many other fungible items (coffee mugs, ballpoint pens). A meta-study on the endowment effect finds that endowment effect is strongest for nonmarket goods, next highest for ordinary private goods, and lowest for experiments involving forms of certain value tokens such as money (Horowitz and McConnell 2002). Similarly, the strength of the endowment effect has also been found to vary across various *circumstances*. Findings in an experiment by Loewenstein and Issacharoff (1994) suggest that the endowment effect is stronger when the commodity is obtained as a result of skill or performance as opposed to chance or random luck.

The endowment has also been linked to *status quo bias* (Samuelson and Zeckhauser 1988), i.e., a preference for the current state that biases people against both selling and buying goods. This

explanation finds some support in a series of field experiments by Hartman et al. (1991).

Critics have challenged endowment effect findings as resulting from flawed experimental designs and “strategic heuristics” (i.e., subconscious applications of usually sensible bargaining habits). Plott and Zeiler (2005) claim that the observed WTA/WTP gap disappears when implementing experimental procedures that control for subjects’ misconceptions about the value of the traded commodity, for instance, by preventing that participants receive a signal that increases the value of the endowment when it is presented to them as a gift by the experimenter. The underlying generalization that the endowment effect is merely an artifact of experimental methodology is a hotly debated issue. As a response to generalizations from Plott and Zeiler’s (2005) study, Isoni et al. (2011) find that the WTA/WTP gap is reduced for mugs, but remains for lotteries even when employing Plott and Zeiler’s (2005) method. To date, no credible conclusion can be drawn from the debate (see also Plott and Zeiler 2011; Klass and Zeiler 2013).

It has also been remarked that the observed gap between willingness-to-pay and willingness-to-sell might not occur in market settings that involve experienced traders and learning opportunities (cf. Knez et al. 1985; Coursey et al. 1987; List 2003). For instance, Coursey et al. (1987) reported results that indeed suggest that the WTA/WTP gap may diminish in such settings. [For a critical discussion of these findings, see Knetsch and Sinden 1987.] Kahneman et al. (1991) ran a set of experiments comparing endowment effects with regard to tokens and consumer goods traded in market setting with repeated interactions that provided learning opportunities. While there was no significant endowment effect on the token market, as soon as the commodity was changed to coffee mugs or ballpoint pens, the market did not clear even in repeated trials. On the one hand, the results indicate that there is no similar effect for money of other value tokens as long as the embodied value is certain (similarly van Dijk and van Knippenberg 1996). On the other hand, strong endowment effects emerged when the traded commodity consisted of consumer goods. In both the market

for ballpoint pens and the market for coffee mugs, selling prices were about twice as high as buying prices. Specifically for the mugs, the median mug holder was unwilling to sell below \$5.25, while the median buyer was unwilling to pay more than \$2.25–\$2.75. Experiments involving repetition (cf. Shogren et al. 1994) and studies that employed a subject pool of very experienced traders (List 2004) did not reliably reduce the endowment effect and, therefore, further dispel the notion that the WTA/WTP gap merely results from inexperience.

Recent research has further expanded the psychological foundation of the endowment effect and, in general, retains the central idea that potential sellers contemplate a large loss, whereas potential buyers contemplate a small gain (Nayakankuppam and Mishra 2005; Zhang and Fishbach 2005; Johnson et al. 2007).

Explaining the Endowment Effect

To date, the cause of the endowment effect remains a topic of contention. Experiments have ruled out many of the potential explanations derived from traditional consumer theory, including income effects, transaction costs, information problems, and market mechanisms (cf. Brown 2005; also compare, Knetsch and Wong 2009).

Richard Thaler (1980) initially proposed that the endowment effect results from the different mental treatment of out-of-pocket costs and opportunity costs, which he argued to be mentally coded as loss and foregone gains, respectively. Through this underweighting of opportunity costs, he linked the endowment effect to the asymmetry in value that Kahneman and Tversky (1979) describe as *loss aversion*: the observation that the negative value of giving up an object is greater than the value associated with acquiring it. The fact that losses are weighted more strongly than objectively commensurate gains might help explain endowment effect observations since “if a good is evaluated as a loss when it is given up and as a gain when it is acquired, loss aversion will, on average, induce a higher dollar value for owners than for potential buyers, reducing the set of mutually accepted trades” (Kahneman et al. 1990, p. 1328).

To clarify the impact of loss aversion, one study specifically investigated whether the gap and low trading volume resulted from a reluctance to sell or a reluctance to buy. The experiment involved three groups. Only the “sellers” received a coffee mug and were asked whether they would be willing to sell the mug at each of a series of prices between \$0.25 and \$9.25. The “buyers” were asked whether they would be willing to buy a mug at the same prices. Finally, the “choosers” were asked to choose at each of the prices between receiving a mug or the money. Recognizing that the “sellers” and “choosers” are in objectively identical situations – deciding at each price between the mug and the money – reveals a surprising pattern: the median reservation prices were \$7.12 for the “sellers,” \$3.12 for the “choosers,” and \$2.87 for the “buyers.” The results suggest that the observed patterns are “produced mainly by owner’s reluctance to part with their endowment, rather than buyers’ unwillingness to part with their cash” (Kahneman et al. 1991, p. 196).

Loss aversion, however, is merely a descriptive construct employed by Kahneman and Tversky (1979) to explain the asymmetry in prospect theory’s value function. It begs the further question as to why individuals experience it. Psychologists have stated that loss aversion may stem from a preference to avoid *regret* and/or to remain *consistent* in decision-making. Since giving up an endowment has a higher potential of causing future regret than not obtaining the endowment, loss aversion may be the result of a regret-avoidance strategy (cf. Gilovich and Medvec 1995; Landman 1987). The desire for consistency (cf. Cialdini et al. 1995) comes into play after the endowment is assigned and a sense of entitlement is established. Being confronted with the contradictory idea to sell the endowment might cause cognitive dissonance, i.e., excessive mental stress or discomfort (Festinger 1957). In this regard, when a seller increases the reservation price (lower WTA), this can be regarded as an attempt to reduce the dissonance created by selling something that had just been acquired and associated with oneself.

Martinez et al. (2011), Lin et al. (2006), and Zhang and Fishbach (2005) have identified

emotions as a moderating variable on the magnitude of the endowment effect. In their studies, when people are induced to positive emotional states rather than negative emotional states, the WTA/WTP disparity is bigger.

Finally, there is some discussion to what extent ownership itself may account for the disparity between the WTP and the WTA or, alternatively, whether tangent explanations such as loss aversion are involved. On the basis of their analysis and experiments, Plott and Zeiler (2005, 2007) argue that ownership in and of itself does not induce a gap between WTA and WTP. However, Morewedge et al. (2009) disentangle ownership from loss aversion in a series of experiments where brokers buy and sell mugs that they do not own. The endowment effect was observed to disappear when buyers were owners and when sellers were not, suggesting that ownership played a role in causing the WTA/WTP difference. One interpretation is that ownership, by way of association and self-identification with the object in possession, may induce endowment effects.

Implications for the Economic Analysis of Law

It has been noted that the endowment effect is “the most significant single finding from behavioral economics for legal analysis to date” (Korobkin 2003, p. 1227). Although the endowment effect is relevant in many areas of law (for a review of the various legal applications of the endowment effect in the law review literature to date, see Klass and Zeiler 2013), the implications for the economic analysis of property law and contract law are especially noteworthy.

Economic Analysis of Property Law: Initial Allocation of Property Rights, Coasian Bargaining, and Remedies

The endowment effect and the associated behavior anomalies of loss aversion and status quo bias have implications for the Coase Theorem. In the presence of endowment effects, the initial assignment of property rights may affect the final outcome, even if transaction costs are insignificant (Korobkin and Ulen 2000). By making a right

holder more reluctant to trade away the item in an efficient transaction, the endowment effect complicates the efficient reallocation of property rights through bargaining. This alters some of the traditional normative implications in the economic analysis of property rights. First, policy-makers might consider allocating property rights to the highest-valuing user – even if transaction costs are low. Second, the endowment effect increases the appeal of damage remedies as compared to property rule protection. If parties who litigate contested entitlements and who are awarded injunctive relief by a court are prone to exhibit endowment effects, they may be particularly unlikely to bargain away their court-approved entitlement, even when the opposing party places a higher value on it (cf. Jolls et al. 1998). Indeed, a series of survey experiments by Rachlinsky and Jourden (1998) indicates that injunctive remedies induce an endowment effect by way of ownership. For instance, when considering the protection of an environmental resource, participants were more insistent on protecting the conservation of the resource than was the case when the same environmental resource had liability rule protection. In contrast to injunctive relief, damage remedies allow higher-valuing individuals to take the entitlement and then pay the market price via the remedy (Korobkin and Ulen 2000). Thus damage remedies may circumvent endowment effects that would otherwise complicate an efficient allocation of rights.

Economic Analysis of Contract Law: Default Versus Mandatory Rules, Explicit and Implicit Opt-in and Opt-out Mechanisms, Standard Form Contracts, and Remedies

First and foremost, the status quo bias interpretation of the endowment effect has implications for the regulation of contract default rules. The endowment effect helps explain the observed “stickiness” of legal default. Even if parties would not likely select an undesirable contract provision, they often neglect to remove this provision when it is assigned to them by default rule. Contracting around undesirable defaults appears to be difficult even when transaction costs are low enough to make it efficient to do so (cf. Korobkin 1998a).

Likewise, the legal endowment effect helps explain why individuals find it hard to opt out of defaults (Johnson et al. 1993). In an experiment, two groups of participants had to choose between alternative automobile insurance policies. One group was presented with a default involving a cheaper policy that restricted the right to sue for pain and suffering resulting from a car accident. Participants in this group were offered the option to instead acquire the full right to sue at an 11% increase of the premium (opt-in). Another group was given a default insurance policy that contained no initial restriction on the right to sue. At the same time, however, participants in this group had the option to forego the right to sue in exchange for a reduction of their insurance premium equivalent to the increase of premiums presented to group one (opt-out). Although standard economic reasoning would predict that the choice between the two options should be the same, the applicable default affected the selection of the policy by participants. While only 23% of participants of the first group elected to opt in to acquire the full right to sue, 53% of the second group elected to retain the full right to sue. Moreover, participants with the restricted right default were willing to pay an 8% average increase of the premium to acquire the full right. When the full right was already the default, however, participants indicated an average willingness to pay 32% more for full coverage than for limited coverage. Overall then, the applicable default affected the preferences of participants in both groups. Note in this regard that also mandatory rules – like withdrawal rights in contract law – can lead to implicit opt-in or opt-out scenarios (Hoeppner 2012). Based on these findings, the endowment effect deserves consideration whenever rule-makers contemplate making use of default rules and opt-out or opt-in mechanisms.

Second, terms and provisions embodied in standard form contracts may likewise serve as reference points for contracting parties in negotiating and drafting contracts. If standard contract form an expectation baseline, they may trigger loss aversion. As a result, even when provided the opportunity to bargain for more efficient terms, contract terms may be biased toward the provided standard forms (cf. Kahan and Klausner

1996). A study by Korobkin (1998b) confirms that when default terms and preexisting form terms offered potential conflicting reference points, negotiation outcomes were biased toward the terms provided in the standard form contracts.

Third, endowment effects have been found to affect contract breach and enforcement decision by way of the applicable remedy. In a laboratory experiment, Depoorter and Tontrup (2012) observed that participants were more likely to reject efficient contract breaches and enforce contracts – even if it is against their financial interests – when the legal default is specific performance, as opposed to damages. In other words, possession of one remedy over the other framed the moral intuition such that the performance of the original contract was experienced more severely to contract promises.

Overall, endowment effects suggest that the statutory framework of contract law is likely to affect the substantive content of contracts even if contract law is based on the notion of private autonomy (freedom of contract).

Conclusion

The endowment effect has been heralded as one of the most important findings of behavioral research (Korobkin 2003). As the empirical findings, methodology and theoretical explanation remain a topic of intense discussion among economists and psychologists, the concept has already been widely applied in both law and economics and mainstream legal scholarship (cf. Klass and Zeiler 2013). As the premises and foundations of the endowment effect continue to be explored, the concept will likely find its way in both theoretical and empirical economic analysis of law.

Energy Governance: EU-Russia Gas Exchanges

C. Locatelli

GAEL, CNRS, Grenoble, INP, INRA, University of Grenoble-Alpes, Grenoble, France

Definition

Strong and lasting interdependencies exist between EU and Russia concerning natural gas exchanges. They imply some questions about energy security from both parties. One could have expected the setting up of more or less institutionalized governance structures – as an institutional system of rules – allowing the management of risks and externalities linked to this interdependence.

On both sides there is a willingness to cooperate. However, to date, the institutional gap between the supply and demand of the cooperation is a constraint to define a governance structure. The question is to know if international standards based on rules generated by the EU are consistent with Russia's institutional environment. The competitive logic and the regulation on which the EU energy policy is founded conflict with the institutional specificities of the Russian economy. This contradiction explains the failure in the European strategy of external governance with Russia. The "gas conflicts" between the EU and Russia can be viewed as the result of the confrontation of different models that structure the natural gas industries of these two countries.

Through this study case, the question of the internationalization of the rules, norms, and more generally an institutional system of regulation is clearly posed.

Introduction

The determinant factors of the relation between Russia and the EU concerning natural gas exchanges are the subject of an impressive literature. The strong and lasting interdependencies that exist between the two zones imply some questions about energy security from both parties. One could have expected the setting up of more or less institutionalized governance structures allowing the management of risks and externalities linked to this interdependence (Escribano 2015). This was the aim of the energy partnership and its prolongation in a strategic partnership, the Energy Charter – the first constraining multilateral treatise in the field of energy, notably in the matter of investments (Wälde 2008; Kustova 2016). It was an attempt to institutionalize a cooperative zone at the level of EU-Russia to respond to the stakes of energy security. However, their painful implementation bears witness to the constraints that weigh on the definition of this zone of cooperation, notably because of strong divergences concerning the preferences of those involved in this relation. The failures in this domain are an

illustration of the problems linked to all attempts to internationalize the norms, rules, and regulations defined in agreement with the national institutional framework.

Interdependences in the Natural Gas Exchanges Between Russia and the EU: Different Preferences and Interests

The interdependences in the natural gas exchanges between the EU and Russia are not questionable. The Russian gas company, Gazprom, is the sole Russian gas exporter to Europe because of its monopoly on exportations by pipelines. It supplies 30% of the EU imports. Since the 1990s, this represents more than 100 Gm³/year of natural gas exported. At the same time, the characteristics of the gas networks (specific assets, non-re-deployable assets according to Williamson's transaction cost theory 1985) founded the interdependence. Thus, Europe (70.8% of total Russian gas exports) is the first and foremost export market for Russia. Because of the infrastructures in place, in the short term, Russia is dependent on this market and cannot reorient its exports toward other destinations. This dependency is especially important for the State since the revenue linked to hydrocarbon exports (oil and gas) is an essential factor of the budget equilibrium and of economic growth.

In this relation of interdependence, the position of the Russian state (interests and preferences) is defined by its role as a hydrocarbon supplier (Romanova 2014). Its main aim is to have stable markets in terms of the quantities exported and the levels of prices. Therefore, it is to secure access to its main export market, the EU (Kratochvil and Tichy 2013). A double aim is imposed on Gazprom: to maintain its market share in the European gas market (the strategic aim of the State, its principal shareholder) and to maximize its income from exports (Boussena and Locatelli 2016; Yang et al. 2016). The result is a concept of demand security. For the EU, given its position as a major importer (the largest at the worldwide level), the question is one of securing its supply in terms of both price and volume. This defines a

concept of supply security in a specific context, a competitive natural gas market.

Perception of Risks Linked to Interdependence

Since the beginning of the 2000s, the perception of a natural gas security problem has emerged both in the EU and in Russia. It is linked to interdependence between the two zones. According to the analysis proposed by Cherp and Jewell (2014), problems of energy security derive from a price risk and a volume risk.

EU: The Risks Linked to the Gazprom Market Power

In the process of liberalization, taking into account the oligopolistic structure of the gas supply, competitive markets are an important condition of the supply security. One of the primary aims of the EU Energy Policy is to limit the market power of all dominant companies, i.e., those capable of distorting competition. From this point of view, Gazprom, which supplies more than 30% of the external requirement of the EU or over 60% in central Europe and in the Balkan countries, represents a specific risk in the eyes of the EU. This is especially important as more than 50% of Gazprom's shareholding is in the hands of the State. Furthermore, the different gas crises between Russia and Ukraine, and the current conflict, pose the question of reliable transit for Russian gas exports to Europe.

Russia: Uncertainties of the European Gas Market

Since the end of the 2000s, the EU gas market has become more volatile and uncertain, notably for its traditional suppliers. The process of liberalization of the gas industries, the surplus supply, and the weakness of the demand linked to the economic crisis, but also to European policies in favor of renewable energies and the drastic drop in the price of oil, have had serious effects. Firstly these factors all led to the emergence of more competitive gas markets, and secondly they resulted in a drop in the price of natural gas of

more than 50% since 2012. These factors are susceptible to put Gazprom's market share in Europe into question. This tendency will continue. In the medium-short term, new LNG suppliers (like the USA, Australia) and uncertainties concerning demand (economic growth, climate policy) mean that the EU is a risky market for Russia and for Gazprom.

These evolutions have led Gazprom to significantly modify its export policy and to adopt strategies that will be different from its traditional contractual framework. Its attachment to long-term take-or-pay (TOP) contracts is known. These contracts have organized its sales to Europe. They have allowed a share in the risks of the price and volumes between the buyer and the seller, notably by guaranteeing the quantities sold annually (removal clause), and guaranteed the development of the gas fields and gas pipelines to Europe. But in the current phase of volatile and uncertain gas markets, Gazprom found itself obliged to reassess this contractual logic. To answer competitive pressures, it had to proceed with more or less major modifications of certain clauses of its long-term TOP contracts (Boussena and Locatelli 2016).

Stakes and Failures of the Governance Structure for Gas Exchanges Between the EU and Russia

The risks linked to this interdependence asked questions about the definition of a governance structure as an institutional system of rules (Lavenex and Schimmelfenning 2009). The primary aim should be the possibility, through cooperation, to limit the extent of conflicts and to stabilize the relations of exchanges between the two zones. On both sides there is a willingness to cooperate. The different attempts to build partnerships, the Energy Charter proposed by the EU or the "Conceptual Approach to the New Legal Framework for Energy Cooperation" developed by A. Medvedev in response to the Charter are some examples. Nevertheless, the cooperation implies some convergence of the actors' preferences. However, to date, the institutional gap

between the supply and demand of the cooperation is a constraint to define a governance structure as demonstrated by the withdrawal of Russia from the process of the ratification of the Energy Charter treaty.

The EU Offer of Cooperation: Building the Markets by the Exporting the Competitive Model

The EU has attempted to manage its relation of dependence with the gas suppliers by the export of its liberal organizational model: governance by competition and EU energy regulation and norms. This form of external governance is an answer to the stakes of security and interdependence through the setting up of a system of common rules and of a high level of institutionalization (Lavenex and Schimmelfenning 2009). In particular, the objective is to overcome the incomplete nature of the competitive reforms concerning the European gas industries. In this way, it is a means to increase the efficiency and the problem-solving capacity of internal liberalization policy (Lavenex 2004). The process of liberalization necessitates opening up upstream of the gas producers and exporting the competitive rules of the EU gas markets. Particularly, the emergence of several gas companies in Russia following the disintegration of Gazprom, potential exporters and therefore in competition on the EU market, would be susceptible to increase the liquidity of the spot markets and render them credible. Next, the aim is to answer the *market failures* that stem notably from an imperfect competition, from the dominant position of certain companies and asymmetric information.

This is the philosophy of the Energy Charter. It is an attempt to build a supranational economic and political integration, to institutionalize an international market system (Andersen and Sitter 2016). Furthermore, it offers guarantees for international investments and allows a competitive principle of nondiscrimination for access to hydrocarbon resources (Haghighi 2007). This access represents a key stake for the “EU gas security” (Boussena and Locatelli 2013). Additionally, the transformation of energy governance of its main suppliers is the essential aim of the EU

energy security strategy (Keating 2012). Finally, on the EU market, the gas supply companies behave in compliance with the EU regulation. In this framework, the EU is capable of “normalizing” their behavior. This defines a power of the EU market according to the terminology of Damro (2012) and Goldthau and Siter (2015).

The Institutional Hiatus: Coherence and Complementarities of the EU Rules with the Russian Institutional Environment

The competitive logic and the regulation on which the EU energy policy is founded conflict with the institutional specificities of the Russian economy. This contradiction explains the failure in the European strategy of external governance with Russia. The questions of coherences and complementarities (Aoki 2001; Amable 2016) of organizational models issued from the economic practices of Western markets with the Russian institutional environment and of their transfer as such remains at the heart of analyses of Russian economic reforms (Hausner 1995; Stiglitz 1999; Murell 2001; Roland 2000; Locatelli and Finon 2003). According to this neo-institutionalist approach EU rules must be coherent or complementary with the Russian institutional and economic environment. It is not the case in the gas sector.

The Russian gas market is characterized firstly by the presence of a State company that is vertically integrated with a monopoly of transport and exports (Gazprom). Some competitive fringes exist on larger and larger segments of the Russian market. This dual market depends on dual prices (administrated and free) and on a strict control by the State of the access to hydrocarbon resources. This reform is that which is compatible with the Russian institutional environment. This latter, marked by the weakness of the market institutions (weakness of the *Rule of Law*, ownership rights that remain poorly defined, regressive fiscal system etc.), seems incompatible with the competitive model and de-integrated organization of the EU gas industries (Locatelli 2014).

This path of reform, and the contestation by the Russian state of the EU nominative power

(Godzimirski 2015; Newmann and Posner 2015), results in increasing divergences in the preferences and interests of these two actors. Their divergent approach to the organization of the gas industries is at the origin of major regulation conflicts. In this context, it is increasingly hard to define and to put in place a governance structure that will be susceptible to manage the gas security problem. Through this study case, the question of the internationalization of the rules, norms, and more generally an institutional system of regulation is clearly posed.

Energy Regulation

Régis Lanneau

Law school, CRDP, Université de Paris Nanterre,
Nanterre, France

Definition

Energy is a fundamental input in modern economies. Its regulation is probably one of the most complex since it is related not only to economic and development issues but also to environmental, geopolitical, and social ones. This entry is using law and economics to inquire into energy regulation, to show the rationale of its regulation and the contemporary challenges it has to face.

Introduction

Man is probably the only animal which is using energy not only to maintain his bodily functions at work but, and by far, for his own comfort. At the end of the eighteenth century and before the industrial revolution, the world was consuming around 250 million tons of oil equivalent (toe); nowadays this figure is reaching 13 giga toe; this dramatic increase also occurred through the development of new energy sources which led to great transitions in energy mix from renewable energy which dominated the eighteenth and nineteenth century to the raise of fossil fuels, especially coal at the end of the nineteenth and oil since the mid-twentieth century. Energy is now a fundamental – not to say a central – input in all production, it is necessary to provide most services, and it is required by both consumers and producers for heating, cooling, cooking, lighting, and using machines and household appliances and of course transportation. Modern life – as we know it – is dependent on energy consumption; so is economic growth and development.

Energy regulation is probably one of the most complex to design, implement, and assess. It is of

course a sensitive political issue since it will not merely have local consequences (for the energy sector) but also powerful systemic ones (e.g., for the economy or for the environment). Moreover, its scope is broader than most other regulation: it not only focuses on production but also addresses questions regarding transportation, distribution, storage, zoning, and use. It can also be addressed indirectly through regulations concerning mines, buildings, cars, safety standards, working conditions, and, of course, the environment. The body of rules is typically huge, poorly systematized, and often cryptic for outsiders. It is probably where law and economics could help to cut some underbrush: the framework it is providing to understand regulations is especially powerful regarding energy regulation (1). Moreover, the economic approach could also help to address some contemporary issues in energy regulation (2).

Before exploring these two topics, it is noteworthy to mention that the idea of energy regulation in the European Union context is not as broad as what the word refers to in the “common language.” Indeed, only natural gas and electricity are concerned, oil benefiting from a special treatment. This could easily be explained using an economic approach of these regulations (infra; 1.1; see also Viscusi et al. 2001), but this restrictive understanding is not helping to stress the fact that energy regulation cannot be addressed energy by energy; it would be better to conceptualize it as an ecosystem in which energy are interlinked.

Why Regulate?

Economic analysis is providing a traditional rationale for regulating: market failures. In the case of energy regulation, it allows for a unifying approach of all regulations which is often missing. The economic rationale is of course not the only one. Political rationales are also powerful considering the central function of energy in modern life.

The Economic Rationale

From an economic point of view, regulations are required if markets are revealing “market failures”

(externalities, market power, imperfect information). This market failure approach to energy regulation reveals itself quite powerful to systematize existing regulations and could explain the “special treatment” reserved to electricity and natural gas. Imperfect information regulation being not fundamental to energy regulation will not be considered here.

Externalities

Producing and consuming energy entail external costs which are not fully considered by rational economic agents either because transaction costs are too high to internalize them through a market or because property rights are not well defined (which of course complexify the analysis to pinpoint “real” externalities). Burning coal, gas, or oil to produce electricity leads to the production of carbon dioxide, sulfur dioxide, and other pollutants; using uranium to fuel a nuclear plant creates radioactive waste. If discharging pollutants (or emitting waste) in the atmosphere is not perceived as a cost, overproduction is to be expected. Even worse, in such system, producers will not have the right incentive to substitute one source of production for another because they will only consider their private costs and not the social cost of their activity.

These externalities are probably the most famous, but many other sources exist:

1. Storage safety (e.g., of oil or gas)
2. Location (e.g., of plants, pipelines, transformer substations)
3. Transmission (because of the physical characteristics of electricity, a coordination is required between producers to power the grid; interconnection of networks also required some coordination)
4. Transportation (because energy fuels are hazardous materials)

Externalities in the energy sector are often addressed through environmental, safety, and zoning regulation. The label should not confuse the lawyer or the economists; these are ways to regulate energy.

Market Power

It is at this level that a “labeled” energy regulation exists. If it is true that market power could also be – and is – addressed *ex post* through competition law (e.g., through the doctrine of essential facilities), some specific characteristics of gas and electricity were considered to require specific forms of regulations.

First, because of their network structure requiring substantial physical infrastructure, this sector often exhibits the characteristic of “natural monopolies” at least for part of these infrastructures (inefficient to duplicate) and not necessarily for production or distribution. However, and before restructuring policies introduced in the 1990s in Europe, it was quite common to face a fully vertically integrated entity responsible for production, transmission, and distribution. Since the market discipline is not effective for natural monopoly, nothing is incentivizing the monopoly to improve its performance or services (for an alternative view and more development on the traditional approach, see Posner 1999). Because of this situation, nationalization and price regulation were often used with all their practical difficulties (for a detail of price regulation technics, see Decker 2015; see also Viscusi et al. 2001).

Second, with the restructuring policies of the 1990s (directives n^{os} 96/92/CE and 98/30/CE for gas and electricity in Europe), allowed by technology improvements, an independent system operator in charge of maintaining and operating the network typically appeared. This operator, quite often a non-profit entity, was and still is often supervised by an independent regulatory agency. These policies were supposed to introduce market discipline with the expected benefits of lowering prices, controlling costs of construction and stimulate innovation (Decker 2015). Their success is mixed (for electricity, see Pollitt 2007).

The Political Rationale

From a political point of view, two main rationales are often mentioned. First, it is required to insure some form of energy independence. Second, territorial cohesion and social justice consideration are also playing a key role in energy regulation.

Energy Independence and Security of Energy Supply

Since energy is the lifeblood of economic systems and especially crucial for defense matter (especially transport of troops and dissuasion), geopolitical consideration often entered in energy regulation. Being, like Ukraine, at the mercy of an energy supplier is perceived as a real geopolitical risk; moreover, limiting risks of an economic paralysis due to a price shock or preventing supply disruption are also considered by energy regulations. The development of the nuclear industry in France proceeds from this logic; the General De Gaulle wanted to insure an energy independence of France. This logic also exists at the level of the European Union. Article 194 TFEU especially mentioned the “security of energy supply” (see also Helm 2002). Council directive 2009/119/EC is “imposing an obligation on Member States to maintain minimum stocks of crude oil and/or petroleum products” (typically 90 days of the average daily consumption of a country).

This security of energy supply could lead to specific regulation in hospital and other public services to make sure that the service will not be interrupted.

Territorial Cohesion and Social Justice

Energy being central to modern life, its provision is often considered a matter of public interest. Reliable access to energy in all parts of the territory is considered as an aim in itself, and the regulators could impose some obligations network operator to make sure that basic provision of energy (electricity especially) is ensured and all parts of the country or a regional zone (typically eastern countries in Europe) are connected. In general, these obligations are leading to compensation (which should not provide an advantage or a disadvantage to the addressee of these obligations). This type of regulation typically does not exist for oil because of its physical characteristics (it can be transported and stored) and relatively secondary importance for basic energy needs.

As a basic need, social fares are also quite common for part of the consumption of energy (the one considered as a “need”). Since these social fares result from a political will, providers

are compensated for the difference between the social fare and the regular one. Moreover, some regulations are introduced to limit the possibility of suppliers to withdraw access to “poor” families unable to pay their bills. Once again, a compensation should then be provided.

Contemporary Issues in Energy Regulation

Energy regulations are still facing numerous challenges from pushing toward a new energy mix to conciliating development and climate change and adapting infrastructures to new needs. It would also have been possible to mention the difficulties of achieving efficient regulations in a domain where lobbying and rent-seeking are considered as a norm. In this section, it will not be possible to address all these issues. Two important challenges will only be quickly considered: first, insuring a real competition between energy producers, so that energy will be supplied by efficient methods, and second, regulations are now trying to promote energy efficiency and are more and more addressing not only suppliers but also consumers.

The Challenge of Insuring Real Competition Between Energy Producers: A Way to Develop Green Energies?

The challenge of insuring an effective competition does not only exist between producers but also among producers of a certain type of energy. We already noted that, in the domain of electricity (for both retail and generation, Decker 2015), restructuring policies achieved mixed results. Ensuring the effectiveness of competition law would already be a first step, and regulated prices in this domain should probably be removed following this logic.

However, the most significant challenge is to ensure an effective competition between energy suppliers, a competition based not on private costs but on social costs. Typically, when regulations are not trying to handle negative externalities resulting from some producers and are also not compensating some others for the positive externalities they are generating, prices are no longer

playing their coordination function. Some costlier energies appear cheaper for consumers which will then not adopt optimal behavior. The energy mix transition (from fossil fuel to renewable energies) which is required by climate change is then stifled (OECD 2012). Even worse, according to OECD, support for the production and consumption of fossil fuel amounted to about USD 55–90 billion every year during the period 2005–2011 for OECD countries (OECD 2013). If such a policy could be easily explained through public choice, it appears clearly inefficient from a macroeconomic point of view. Removing these support measure would certainly spur innovation in and consumption of green energy by lowering incentives to produce and use fossil fuels. It would also allow to reduce and improve the efficiency of subsidies to green energy and green technologies (Harris 2006). Note that it would also be required to compute the environmental cost of each and every technology to assess the “real” price which, considering valuation methodology (see Markandya et al. 2002), will lead to lots of contention.

Because of some form of path dependency, it is nevertheless not certain that such radical evolution of regulation is to be expected in the near future or will happen smoothly (Unruh 2002).

Energy Efficiency and Regulation of Its Use

If consumers and producers were entirely rational, they would switch to energy-efficient technology when this technology is also cost effective. If it is not the case, they will not necessarily invest in energy-efficient machinery, appliances, cars, or even buildings. This situation could arise because of implicit discount rate. The consumer will choose an appliance or a car or consider some improvement of his house if and only if she is perceiving it as a good investment. Nevertheless, energy-efficient technologies are often costlier than other technologies, and integrating the private future benefits on energy costs is not sufficient to lead consumer to make such a choice. Indeed, these benefits should be discounted at their present value, and if the implicit discount rate is too high compared to a “normal” discount rate, consumers will not adopt an optimal

behavior. Imperfect information could also explain this situation. From this point of view, building codes and fuel efficiency standards could make sense if and only if they are designed adequately. A less paternalist approach would lead to efficiency labeling which is not without its own side effects.

This type of regulation has only indirect effects on energy generation or distribution but could lower the demand for energy and hence the externalities generated (see Mitchell and Woodman 2010). Considering the difficulties to achieve an optimal regulation relative to energy production, this option should not be disregarded.

Conclusion

From a law and economics point of view, energy regulation should be addressed with the idea that what is to be regulated is a full ecosystem and not some sector-specific problems. The market failure approach of regulation provides an interesting starting point to describe and criticize energy regulations. It also enlightens the fact that in this domain of essential complexity, information requirement for an efficient regulation is gigantic. It is nevertheless well accepted that direct subsidies to fossil fuel should be avoided.

Entrepreneurship

Marta Podemska-Mikluch
Faculty of Economics, Gustavus Adolphus
College, Saint Peter, MN, USA

Definition

While one could search in vain for a definition of entrepreneurship acceptable to all entrepreneurship scholars, dominant approaches share a number of characteristics. Typically, an entrepreneur is portrayed as an agent of change who operates in a world of incomplete and dispersed knowledge while facing uncertainty about the future. What differs in the various conceptualizations is the mechanism of overcoming uncertainty and knowledge problems. The three leading approaches portray entrepreneurs as dealing with these challenges through either alertness, creativity, or judgment, with new streams of literature adding hypothesis testing and effectuation to the list. While disagreements on the particulars of what entrepreneurship is and what role it plays in economic theory continue, economists now

agree on the strong relationship between entrepreneurship and institutions. In particular, it is now well accepted that whether entrepreneurship produces economic growth depends on the institutional context. The other side of this relationship – impact of entrepreneurship on institutions – only begins to receive attention, as does the role of entrepreneurship outside of the conventional market setting.

Introduction

Economists have yet to agree on a single definition of entrepreneurship. Thinkers interested in entrepreneurship originate from diverse perspectives and evoke entrepreneurship to solve distinctive theoretical puzzles. As a result, there is no agreement in the literature on what entrepreneurship is and what role it should play in economic theory. This being the case, anyone interested in entrepreneurship theory should not feel discouraged. The different conceptualizations of entrepreneurship share a number of characteristics. For example, in all cases, entrepreneur is portrayed as an agent of change who operates in a world of incomplete and dispersed knowledge while facing uncertainty about future. It is the mechanism of dealing with uncertainty and knowledge problems that differs in the different conceptualizations of entrepreneurship. The leading approaches portray entrepreneurs as being able to overcome these challenges due to (1) being equipped with alertness to previously unnoticed profit opportunities (Kirzner 1973), (2) being creative and having leadership skills (Schumpeter (1911) 2008, (1943) 2013; Shackle 1972), (3) exercising entrepreneurial judgment (Knight (1921) 2012; Casson 1982; Foss and Klein 2012), (4) experimentation akin to scientific hypothesis testing (Harper 1996), and (5) effectuation (Sarasvathy 2008).

Interest in entrepreneurship theory has been on the rise for the last three decades (Elkjaer 1991; Venkataraman 1997). This is true not only in economics but also in management. For example, in 1987, Entrepreneurship Division was added to the Academy of Management, and now

entrepreneurship has its own code (L26) in the Journal of Economic Literature classification (Foss and Klein 2012, 23). As can be learned from the numerous sources offering an in-depth survey of the history of entrepreneurship thought (Blaug 1998; Praag 1999; Brouwer 2002), the tradition is not new; its origins can be traced all the way back to Richard Cantillon's 1755 distinction between entrepreneur, employee, and landowner with entrepreneur being characterized as carrying the risk (Cantillon (1755) 2015). Cantillon treated the economy as an interconnected whole where coordination and adjustment were secured through competition and entrepreneurship. Even though other thinkers, for example, Jean-Baptiste Say and John Stewart Mill, followed Cantillon's footsteps and also contributed to the theory of entrepreneurship, the concept disappeared from economic theory almost completely by 1870 (Blaug 1998). Undeniably, while the interest in entrepreneurship is now growing, it is yet to be incorporated into mainstream economic theory, and the disagreements on its relevance continue (Foss and Klein 2012, 24).

Despite their status as idiosyncratic outsiders, two twentieth-century thinkers are associated with entrepreneurship in economics and management literatures: Joseph Schumpeter and Israel Kirzner. Equally well known is the difference in their portrayals of entrepreneurship: while Schumpeter sees entrepreneurship as a disruptive force that pulls the economy away from equilibrium, Kirzner views it as a coordinating, equilibrating force. Partially because neither of these theories made significant in ways into mainstream economics, Casson (1982) and Klein and Foss (2012) suggest a third approach, that of Frank Knight. To understand key aspects of each approach, and how they differ, a closer look is warranted.

Entrepreneurship as Creativity and Leadership

Schumpeter's entrepreneur is an innovator, an agent of change, and a disrupter. Entrepreneurship is the force that breaks away from the routine and

drives economic change. Schumpeter first introduced the concept of an entrepreneur as an innovator in his groundbreaking *Theory of Economic Development* (Schumpeter (1911) 2008). While Schumpeter was fascinated by Walras and by the general equilibrium theory, he found the static analysis of neoclassical economics to be incapable of explaining economic change. In response, he aspired to offer a process theory akin to that of Marx. Schumpeter described the tendency toward the equilibrium – the key concept in neoclassical economics – as “the circular flow of economic life” where nothing new ever happened. He reasoned that in a theoretical apparatus of general equilibrium, where the circular flow of production and distribution was in balance, there is no room for novelty. Only when entrepreneur is introduced, novelty enters the model. Entrepreneurs break away from the circular flow by making nonroutine choices, by arranging resources into “new combinations.” Without entrepreneurship, economy remains in a state of circular flow. So entrepreneurship is necessary in order to give an endogenous account of economic change; it is the driving force of economic development.

In explaining how entrepreneurs innovate, Schumpeter listed five distinct categories of “new combinations”: (1) introduction of a new good, this encompasses introducing a good to unfamiliar customers or creating a higher-quality good, (2) creation of a new method of production, (3) the opening of a new market, (4) the capture of new sources of supply, and (5) a new organization of industry (Schumpeter (1911) 2008, 66). Time is the essence in Schumpeter's conceptualization because time turns innovation into routine. The distinction between innovation and routine, between new and old, is the distinguishing factor between entrepreneurs and other economic agents. Once entrepreneurs build up their business and stop carrying out new combinations, they stop being entrepreneurs and turn into managers. In creating new combinations, entrepreneurs perform a function that is separate from that of capitalist, landowner, laborer, manager, or even an inventor. A manager could also be an entrepreneur but not every manager is an entrepreneur and vice versa. In addition, as can be implied from the five

categories of new combinations, Schumpeter recognized that innovation and invention differ: the former requires leadership and will, the latter requires intellect. For economic analysis the one that matters is innovation because “as long as they are not carried into practice, inventions are economically irrelevant” (Schumpeter (1911) 2008, 88).

Leadership, which manifests itself as the willingness to break away from the routine, is a key characteristic of Schumpeter’s entrepreneur. It is the entrepreneurial leadership that in Schumpeter’s framework provides the creative energy that propels societies in new directions and breaks existing structures. Therefore, to Schumpeter, entrepreneurship is the locus of leadership in a free society. As later developed in “capitalism, socialism, and democracy,” leadership and entrepreneurship are the forces behind creative destruction – a force that creates and destroy the structures of the economy in an ongoing process of innovation and change, making it the essence of economic development (Schumpeter (1943) 2013).

Entrepreneurship as Coordination

While Schumpeter’s entrepreneur is usually considered a creative and disruptive force, Kirzner’s entrepreneur is a middleman, an arbitrager. Entrepreneurship to Kirzner is a force that drives the market toward equilibrium, not away from it (Kirzner 1973). The entrepreneurial function is first and foremost that of securing coordination among market participants. In his most cited book, *Competition and Entrepreneurship*, Kirzner offers a simple definition of the “pure” entrepreneur as observing “the opportunity to sell something at a price higher than that at which he can buy it” (Kirzner 1973, 16).

Kirzner’s entrepreneur operates in a Hayekian world of dispersed knowledge, knowledge that is specific to time and place. In such a world, coordination is a puzzle: how is it possible that despite being equipped with different knowledge, individuals are able to find opportunities for mutually beneficial transactions? (Hayek 1937, 1945). Clearly, in the world of perfect knowledge, people

would be aware of the full spectrum of options that might be available to them, and there would be no errors for entrepreneurs to capture. Only in the world of incomplete knowledge, some buyers pay prices that are too high, and some sellers accept prices that are too low. By remaining alert to these errors, the entrepreneur observes the differences in prices and profits from reconciling them.

Just like Schumpeter, Kirzner too is critical of mainstream economics and offers a critique of contemporary price theory, in particular the Robinson-Chamberlin model of monopolistic competition (1973). He argues that neoclassical economists are overly committed to the equilibrium framework and pay no attention to the market process, the process through which equilibrium and coordination are generated. While the neoclassical price theory pays no attention to entrepreneurship, Kirzner argues that entrepreneurship is the driving force of the market economy. Along with other economists of the Austrian tradition, Kirzner maintains that the neoclassical approach relies on overly restrictive assumptions. In their view, prices encountered in a market economy are not equilibrium prices, but rather they should be considered emergent exchange ratios that evolve as entrepreneurs seek to discover arbitrage opportunities. Through the process of discovering arbitrage opportunities, entrepreneurs capture profits, and the economy moves toward the equilibrium. In contrast, if the process of adjustment is viewed as automatic, there is no role for the entrepreneur in the model. What is puzzling and interesting to Kirzner is assumed to happen automatically in the price theory framework.

I will thus argue that the dominant theory, by emphasizing certain features of the market to the exclusion of others, has constructed a mental picture of the market that has virtually left out a number of elements that are of critical importance to a full understanding of its operation. (Kirzner 1973, 4)

While on the surface Kirzner’s approach might appear to be completely different from that of Schumpeter, a number of authors view them as complementary (Hébert and Link 1988; Boudreaux 1994; Choi 1995). For example, Boudreaux argues that the two approaches are

complementary in that they both capture the distinct aspects of the competitive market process. According to Boudreaux, if economists adopted a broader notion of equilibrium – one that include quality adjustments and technological and organizational improvements in addition to price adjustments – then Schumpeter's entrepreneurship could also be viewed as an equilibrating mechanism (Boudreaux 1994). In his own reconsideration of the two approaches, Kirzner argues that entrepreneurs are both alert and creative but that only alertness is relevant to the analysis of the market process (Kirzner 1999). Alertness renders entrepreneurship the driving force of the market process. In contrast, boldness, creativity, and self-confidence are psychological traits. While being bold and creative might contribute to entrepreneur's success, these characteristics are not relevant to entrepreneurship's equilibrating function. It is alertness that coordinates market activities, not boldness or creativity. According to Kirzner, Schumpeter's psychological portrayal of the entrepreneur might be an accurate reflection of real-world entrepreneurs. However, these are secondary features that simply give entrepreneurs an edge, whereas alertness is foundational. Moreover, Kirzner reasserts that entrepreneurship must be viewed primarily as coordinating, not disruptive. Without entrepreneurship, it is impossible to explain market coordination.

While disagreement between Schumpeter and Kirzner received significant attention in the literature, Manne notes that a more prominent and far-reaching disagreement occurred between Kirzner and Demsetz (Manne 2014). Demsetz defended price theory and that entrepreneurship is not a separate category of market activity (Demsetz 1970). Subsequently, Tyler Cowen notes that the discussion of entrepreneurship versus optimization is alike to that between philosophy and poetry (Cowen 2003).

Entrepreneurship as Judgment

Foss and Klein abandon the discussion of creativity versus alertness and instead suggest that Knight's conception of entrepreneurship, as

judgmental decision-making under uncertainty, provides a better explanation of the entrepreneurial function and can be most smoothly integrated with the economic literature on the firm (Foss and Klein 2012). The authors define judgment as "decisive action about the deployment of economic resources when outcomes cannot be predicted according to known probabilities" (Foss and Klein 2012, 38). They view judgment as different from alertness because alertness tends to be passive, whereas judgment is active. As the authors explain, alertness is the ability to react to existing opportunities, while judgment refers to the creation of new opportunities (Foss and Klein 2012, 39).

They focus on the conceptualization of entrepreneurship as judgment because they see it as a natural complement to the theory of the firm. To capture this relationship, they turn to Knight who linked profit and the firm to the existence of uncertainty (Knight [1921] 2012). Entrepreneurship requires making a judgment about the most uncertain events, and due to this utmost uncertainty, entrepreneurial judgment cannot be sold on the market, but rather becoming an entrepreneur requires starting a firm. Judgment, as considered by Foss and Klein, pertains employment of resources; therefore, entrepreneurial decision-making is ultimately a decision-making about the employment of resources. Interestingly, and to further separate themselves from Kirzner, the authors argue that opportunities for profit do not exist independently, they are not out there, waiting to be discovered. Rather, they need to be created and manifested in action.

Entrepreneurship in Action

Numerous authors have expanded on Knight, Kirzner, and Schumpeter in a manner that allows us to better understand the mechanism of how entrepreneurs actually deal with uncertainty. One of these authors is David Harper, who adopted the Popperian growth of knowledge approach to illuminate entrepreneurial learning (Harper 1996). Harper postulates that market entrepreneurship is akin to scientific hypothesis testing. Similarly to

Foss and Klein, Harper is not persuaded by the notion of passive alertness and believes entrepreneurial opportunities are not discovered but must be created. Due to uncertainty and human fallibility, there is no way of knowing whether the new opportunity is going to be a success or a failure. Therefore, each time entrepreneurs launch a new product or venture, they are testing a hypothesis. If businesses succeed, the hypothesis is unfalsified, and it remains unfalsified as long as there is sufficient interest to sustain the venture. As in science, rejected hypothesis are valuable: they contribute to the growth of knowledge.

Accordingly, Harper defines entrepreneurship “as profit-seeking activity aimed at identifying and solving ill-specified problems in structurally uncertain and complex situations. It involves the discovery and creation of new ends–means frameworks, rather than the allocation of given means in the pursuit of given ends” (Harper 1996, 3). By exploiting similarities between the market process and the process of scientific knowledge formation, Harper sheds light on how entrepreneurs acquire, use, and disseminate new, often tentative and conjectural, knowledge. Following Loasby, Harper notes that the relationship between market process and scientific progress is not a coincidental metaphor but both describe the same process: the growth of knowledge (Loasby 1989).

Harper argues that since scientists and entrepreneurs are problem-solvers, their activities must be described in terms of human ends and purposes. This systematic approach to uncertainty makes Harper’s entrepreneur significantly different from Schumpeter’s and Kirzner’s conceptualizations. While Schumpeter and Kirzner highlighted the nonrational and intuitive aspects of entrepreneurial behavior, Harper argues that rationality and critical methods of error elimination are crucial for acquiring new knowledge.

Saras Sarasvathy offers parallel insights into how entrepreneurs deal with uncertainty. Sarasvathy contributes to the entrepreneurship scholarship a notion of effectuation, which she defines as an inverse of causation. Causal thinking involves selecting means most suitable for the achievement of predetermined ends. Effectuation, in contrast, starts with given means and seeks to

create new ends. While economic agents are typically portrayed as employing only causal thinking, Sarasvathy’s entrepreneurs combine causal and effectual thinking. They act based on what they know about themselves and others, focus on the control of resources at hand, and on what kind of effects are within their reach. As they generate the alternatives, they simultaneously assess the qualities of different ends. To Sarasvathy, entrepreneurship and effectuation are crucial in opening economics to imagination and novelty, which in turn has significant analytical implications. For example, Sarasvathy argues that while economists have traditionally assumed existence of such artifacts as firms, organizations, or markets, the creation of these facts cannot be explained without effectuation (Sarasvathy 2001, 2008).

Entrepreneurship and Institutions

Given the interest in the relationship between entrepreneurship and economic growth (Aghion and Howitt 1990; Wennekers and Thurik 1999; Blanchflower 2000), impact of institutions on entrepreneurship begun to attract increasing attention. In his now classic paper, Baumol considers the impact of institutional environment on the relative payoffs to different forms of entrepreneurship (Baumol 1990). According to Baumol, not all forms of entrepreneurship are productive. For example, rent seeking, litigation, and warfare are entrepreneurial in nature but have a negative impact on economic growth. When institutional environments renders payoffs to unproductive or destructive activities higher than payoffs to productive entrepreneurial activities, entrepreneurship does not translate into economic growth. In other words, Baumol argues that changes in the extent of productive entrepreneurial spirits are not random but depend on the rules within which entrepreneurial activity takes place. In a similar spirit, Sautet notes that “what is generally missing in countries with lackluster economic performance is not entrepreneurship as such but the right institutional context for entrepreneurship to take place and to be socially beneficial” (Sautet 2005).

It is now well accepted that institutions determine whether entrepreneurship contributes to economic growth. However, as noted by Boettke and Coyne, to simply point out the set of institutions most conducive to productive entrepreneurship is not the same as actually implementing these institutions (Boettke and Coyne 2003). This opens the question of what drives institutional change. While various theories of institutional change can be found in the literature, Wagner places institutions along with market phenomena as an outcome of entrepreneurial action and suggests bidirectional, entangled relationship between entrepreneurship and institutions (Wagner 2009, 2010). In a similar vein, and building upon the examination of institutional entrepreneurship through the lenses of institutional theory and institutional economics (Pacheco et al. 2010), Kuchař uses the emergence of surrogate motherhood market to illustrate how entrepreneurs drive institutional change by challenging existing institutional legal ordering and common interpretations of social phenomena (Kuchař 2016).

Directions for Future Research

If Sarasvathy and Venkataraman are correct in suggesting that we might have miscategorized entrepreneurship as a subfield of management and economics when it is a social force akin to democracy or scientific method (Sarasvathy and Venkataraman 2011), then scholars interested in pursuing entrepreneurship research need not worry about a shortage of research streams. Sarasvathy and Venkataraman go as far as to argue that entrepreneurship is not a subject of social inquiry but a method of human action. There are reasons to believe that they might be correct in anticipating an entrepreneurship-centered revolution, as evidenced by the growing interest in entrepreneurship and the emerging literature on entrepreneurship in unconventional institutional setting, i.e., social, political, institutional, and cultural entrepreneurship (Dacin et al. 2010). Another approach to considering entrepreneurship's role beyond the market setting is that of Podemska-Mikluch and Wagner: entrepreneurial

coordination across divergent institutional frameworks, not only within them (Podemska-Mikluch and Wagner 2017). If this broader understanding of entrepreneurship were to take off, one area of economic theory prone to rethinking would be market failure literature because its conclusion relies on the absence of entrepreneurship in any form, be it conventional, institutional, political, or cross-institutional.

Environmental Crime

Giuseppe Di Vita

Department of Economics and Business,
University of Catania, Catania, Italy

Abstract

To study environmental crime in a perspective of law and economics, it is necessary to identify the protected species from an economic point of view and at the same time to give a legal definition of this kind of criminal behavior. The list of sanctions and their effective deterrence effects in cases of environmental crime are addressed in the final part of this entry.

Definition

Environmental crime is a behavior harmful for the natural environment and its population that is punished with criminal sanctions, according to the nature of the protected species and the type and magnitude of present and future damage.

Environmental Crime

Interdisciplinary issues are hard to approach because they involve different kinds of knowledge with the use of specific terminology; this is particularly true in the case of environmental crime. The analysis moves from the concept of environment as the object of legislative protection and then follows with the definition of

environmental crime. This is not an easy task because even within the legal doctrine there is no unanimous view of the concept of environmental crime, and technical language is not the same for lawyers and economists. The analysis follows with a list of the criminal sanctions that may be applied as a consequence of public enforcement of criminal environmental law against the violators of such rules. In conclusion, the deterrence effects of criminal sanctions are studied in practice, considering the results of empirical studies performed. (See Gray and Shimshack (2011) for a recent survey of the literature on empirical analysis on enforcement of criminal sanctions.)

Environment

From the economic point of view, we should define the interest protected by the law and the reasons why the policy maker (or legislator) chooses to punish illegal behavior against the environment by applying criminal sanctions.

The problem of an optimal use of the environment and its protection originates from its nature of public good (Siebert 1992) and its characteristics of non-excludability and non-rivalry. The inability of the market to determine an equilibrium price may be due to the social costs associated with the private use of the good (as in the case of pollution emissions), or the collective nature of the benefits, that make the excludability cost extremely high and the price market equal to zero (e.g., the case of biodiversity preservation). In the first case, the self-interest of individuals determines an exploitation of the environment, while in the second hypothesis, the indivisibility of the benefits makes the individuals unwilling to pay for this kind of good. Whenever the existence of a source of market failure is present, the market produces an inefficient allocation of resources (Bator 1958), thus rendering necessary the adoption of some economic and legal policy, to bring the system as close as possible to a situation of Pareto-optimal market allocation. A wide spectrum exists of possible measures that it is possible to implement in order to correct the inefficiencies of the market, such as Pigouvian taxes, standards,

tradable permits, Coasian solution, and creation of an institution (Faure 2012; Tietenberg and Lewis 2012). This study considers only the cases where the inefficient allocation of environmental assets is punished by means of criminal sanctions.

The main reason for committing a crime against the environment is the saving gained by avoiding a costly compliance to the regulation implemented, adopted with the aim of preserving the environment. The individuals who follow their self-interest, thereby breaking the environmental law, worsen social welfare, overexploiting the environment with irreversible harm for future generations. The economic benefits for violators increase according to the degree of stringency of the legislation (Almer and Goeschl 2015).

From the legislative and court point of view, the kind of remedy is commensurate with the gravity of the behavior to the environment (Rousseau 2009). So the private remedies of repayment for damage or injunction are confined to the less important cases where the consequences of illegal behavior are limited to the parties involved (e.g., the noise in a private apartment). The sources of market failures render the use of standard civil remedies difficult (like using the strict liability regimes, see Sigman 2010) and the administrative fines inadequate.

In the case of private goods, it is sufficient to design the property rights properly in order to bring the system to the optimal path, allowing the victim of damage to file the case in the court and to be reimbursed for the damage, thus indirectly promoting the private enforcement of environmental law. This efficient mechanism cannot be used in the case of public goods because of the incomplete appropriability of the benefits and the multiple offensive environmental damages that go beyond the individual dimension and involve collective values and the welfare of future generations.

To protect environmental goods like air, soil, and water, it is necessary to adopt policies promoting the use of devices to abate the level of pollution and/or to implement more environmentally friendly technologies together with other measures to preserve biodiversity and to avoid climate changes, domestic and trans-boundary pollution, illegal waste disposal in landfill,

pollution emissions, and so on. Often, such kinds of good cannot be efficiently protected by using the standard private law remedies (like injunction to avoid future damages and the condemnation of the author of the offense to pay past damages), in consideration of their characteristic as public good, requiring stronger measures from the policy maker, like a public enforcement of the law, that may only indirectly protect the private rights involved. (About the “civil enforcement tools” of environmental law, see Glicksman and Earnhart 2007.)

Environmental Crime

The “enforcement pyramid” (Ayres and Braithwaite 1995), i.e., the graduation of penalties for illegal behavior that could be applied to protect the environment, is made up of civil sanctions, administrative fines, and criminal sanctions. Although all the kinds of sanctions have as common denominator the protection of the environment by means of punishment of the violator and reimbursement of the damage, the first two kinds of enforcement of environmental law have as their principal aim to deter the violator and compensate the offended individuals, in contrast with the criminal sanctions that have as their main goal to punish the violator.

Among the civil sanctions to implement environmental law, the “citizen’s suit” deserves a special mention; it may be defined thus “... Citizen suits are court proceedings brought by citizens who seek to enforce public rights. In the environmental arena they are cases brought to enforce the rights or obligations created by environmental laws. They are civil as opposed to criminal cases. While citizens’ suits are often brought against government authorities this is not a definitive feature ...” (Mossop 1993). This measure to implement environmental law has been extensively used in wealthy (Naysnerski and Tietenberg 1992) and less developed countries, precisely since 1958 in the Czech Republic (Earnhart 2000). This kind of law enforcement is based on the citizens’ cooperation to protect the environment and may be useful in minor cases of

law infringement. (Regarding the effects of alternative policies increasing reliance of self-reporting by polluters, see Farmer 2007.)

The step immediately next to the first in the enforcement pyramid consists of the administrative fines that may be applied without any judge’s intervention; their implementation is devoted to public bodies of the state. The problem is that the dissuasive capability of administrative sanctions could be inefficient to punish and deter the more dangerous behavior to the environment. (See on the optimal level of environmental fines the interesting paper by Rousseau and Kjetil 2010.)

In general, it is possible to note that criminal proceedings are, in contrast to civil proceedings, initiated by the government or by public authorities rather than offended individuals. This kind of public enforcement of environmental law requires a high standard of proof, involving fundamental individual rights constitutionally protected (like individual freedom) and moral-social stigma consequent to an application of a criminal sanction.

The environmental crime may be defined from the legal point of view as a crime against the environment or the violation of an environmental law (Clifford and Edwards 1998). (Clifford and Edwards (1998) moreover propose a broad philosophical definition of an “environmental crime” as an act committed with the intent to harm or with a potential to cause harm to ecological and/or biological system and for the purpose of securing business or personal advantage. See Eman et al. (2013) for an updated survey of the definition of “environmental crimes” in general and within the European Union. For a criminological analysis of environmental crime, see Huisman and Van Erp 2013 and Lynch and Stretesky 2014).

Although from the legislative point of view it is simple to say what is an environmental crime, among the international community of law scholars, there is no unanimous definition of this concept; nevertheless, the phrase “environmental crime” is used in several international agreements and national legislation.

Here, we may underline the increasing relevance of the trans-boundary dimension of environmental protection (e.g., air, waste, water, global warming; green crimes include air

pollution, water pollution, deforestation, species decline, the dumping of hazardous waste, etc.). This indicates the need for the international community to define this concept univocally. The main obstacle to this aim is that the identification of environmental goods protected by criminal sanctions depends on the socioeconomic condition of each single country. So you may expect countries at the same stage of development to be more prone to adopt similar or identical legislation and enforcement systems, because their relationship between per capita income and pollution is the same. (About the relationship between per capita income and polluting emissions and the relevance of legal family in explaining the environmental quality levels at different stages of growth, see Di Vita (2008).) Developing countries are not able to use their scarce resources to protect the environment fully. These considerations could be of help in explaining why the delimitation of environmental crime differs among countries.

Criminal sanctions for violation of environmental law constitute a novelty introduced in the 1980s of the last century, with an increasing incidence in recent years (Billiet and Rousseau 2014; Goeschl and Jürgens 2014). Since the 1970s criminal sanctions to protect the environment have become a measure extensively used in the United States and later on in the European Community (Almer and Goeschl 2010). (For an updated survey of “environmental crime” within the European Union, see Öberg (2013).) In the European Union, the criminalization of environmental law enforcement has been strengthened by the European Directive 2008/99/EC (Billiet and Rousseau 2014). More recently, since the mid-1990s, some European countries have introduced administrative sanctions as a complement of criminal fines (Faure and Svatikova 2012; Faure 2012). Administrative measures have the advantage of being more flexible than criminal proceedings so that the enforcement of environmental law may be pursued at lower cost. Even in the former Eastern European countries, the environmental laws are beginning to be protected by the introduction of criminal sanctions (Eman et al. 2013).

Australia is a country where the protection of the environment by means of criminal sanctions

has a long tradition and since 1979 has played a leading role in criminal justice processing of environmental offenses through the New South Wales Land and Environment, being probably the first nation to introduce environmental courts (Walters and Westerhuis 2013). Among the so-called BRICS countries, Russia seems to have experienced a reduction of crimes against the environment (according to domestic statistics), although some people suggest that together with a decrease in ecological crimes and offenses, there is some increase of latency within the field of ecological crime. Recent research suggests that one of the major profiles of environmental crime counteraction could be the nongovernmental ecological control system development adopted in Russia that is devolved to both municipal and social ecological control. This raises some doubt about the degree of enforcement necessary to achieve the optimal level of environmental protection (Anisimov et al. 2013).

Even China, one of the most dynamic economies among the developing countries, has recently levied criminal sanctions to punish violators and deter future infringements of environmental law (Zong and Liao 2012). In the African continent, protection of the environment from criminals is not so widespread for the economic considerations discussed previously. Nevertheless, this may represent a missed opportunity to preserve one of the largest green lungs of the world and an inexhaustible source of biodiversity.

The key point of view to consider the importance of environmental crime is the dynamic effects of this kind of sanction in bringing the economic systems toward a more sustainable path to preserve the environment and render the stock of environment useful for future generations.

Criminal Sanctions To Punish and Prevent Behavior Harmful to the Environment

Based on the previous considerations, it is clear that the state has to choose whether to punish some illegal behavior with a criminal sanction in

consideration of the interest protected and the offensive magnitude of present and future damages. In the case of civil remedies to enforce the environmental law, the costs burden the citizens, with limited expenses for the public sector of the economy (state administration and its ramifications). The criminal sanctions are applied because it is assumed that they raise the level of environmental protection, with high costs to the public sector of economy in terms of investigation and imposition of penalties. The enforcement costs are relevant under binding budget constraint.

Shavell (1985, 1987) has identified five conditions that should be fulfilled to justify the application of nonmonetary sanctions for efficient criminal deterrence. Such conditions are (i) the probability of insolvency of the violator, (ii) the possibility that the criminal is able to avoid paying the monetary sanction, (iii) the illicit earnings for the private agent in infringing the environmental criminal law, (iv) the potential future damage to the environment, and (v) the magnitude of the damage. His conclusion is that the criminal sanctions are worth applying only when these five conditions are strong enough to outweigh the social costs to deter, punish, and hold in jail the authors of environmental crimes (Billiet and Rousseau 2014).

In a general theoretical framework, Emons (2003, 2007) found evidence that criminal sanctions should be applied in the case of repeat offenders, punishing the less harmful violation of the law with monetary penalties; escalating penalties are used not to make the criminal career less attractive but to make being honest more attractive. Despite these theoretical findings, the empirical question is whether the use of escalating sanctions based on offense history is valid when the benefit of crime and the probability of apprehension are high.

The recent guidelines of US sentences suggest inflicting a short period of imprisonment when the environmental crime leads to severe damage (e.g., an illegal dump of waste, river pollution, etc.). In accordance with previous theoretical findings, O'Hear (2004) reports that in Australia, the prison sentences for environmental crime

have been limited to the most serious offenses to the environment.

The sanction for a criminal defendant varies according to the crime and includes such measures as the sanction of death, not applicable in cases of environmental law infringement. Incarceration is a period of time that the violator spends in jail, as a consequence of a criminal sentence. Probation is the period during which a person, "the probationer," is subject to critical examination and evaluation. It is a trial period that must be completed before a person receives greater benefits or freedom. (The probationer criminal sanction could be considered quite similar to the suspended sentences that have a lower immediate effect but tend to deter future criminal behavior (Billiet and Rousseau 2014).) Community service is the period of time that the convicted spends doing civil services instead of jail or at the end of the period of imprisonment. Finally, monetary fines are monetary sanctions applied by the courts as a conclusion of a criminal proceeding (for a more complete explanation of the characteristics of criminal sanctions, see Öberg 2013).

Deterrence Effects of Criminal Sanctions

In the introduction we assume that the criminal sanctions are applied in cases of extremely offensive behavior toward the environment. The underground message is that criminal sanctions possess the greatest deterrence capacity to dissuade further environmental damage. The axiom that criminalization raises the level of environmental quality has been questioned several times (Stigler 1970; Polinsky 1980; Andreoni 1991; Heyes 1996), in consideration of greater costs for the use of criminal sanctions and the negative substitute effects on civil and administrative fines.

Recently, Goeschl and Jürgens (2014), moving from the initiatives of the European Commission to prevent environmental crimes, have shown that an increase in the criminalization level does not necessarily lead to higher environmental quality. The greater the area of criminal responsibility for environmental law violation, the lower will be the enforcement by using alternative measures.

Based on these considerations, the debate is shifted into the arena of applied studies.

Cherry's (2001) empirical analysis found strong empirical evidence that financial penalties have a deterrence effect stronger than prison sentences and that monetary sanctions imply a lower social cost to punish those responsible for crimes and to prevent future damages. The limitation of Cherry's study is that crimes against the environment are not considered but illegal behavior in general.

Faure and Heine (2005), in their research on the enforcement of environmental crimes in Europe, find that monetary sanctions are more widespread than criminal sanctions in the Old Continent. Almer and Goeschl (2010) found a positive relationship between environmental crime prosecution and the deterrence effect. This result is reinforced by the outcomes of another empirical study conducted, using microeconomic data, in Germany regarding in particular waste crimes, where persecutors faced inelasticity of 4% of resources devoted to environmental offices in response to a unitary increase in environmental crimes (Almer and Goeschl 2011).

Faure and Svatikova (2012) performed an empirical analysis on the effects of criminal sanction deterrence of illegal behavior against the environment when the penalty is used together with the administrative process to enforce environmental law. Their analysis is based on the theoretical assumption that to enforce environmental law, having a budget constraint, it is more efficient to use administrative fines, instead of criminal sanctions, because they are more flexible and cheaper than criminal proceedings.

Their evidence, based on a dataset available for four Western Europe nations (the Flemish Region, Germany, the Netherlands, and the United Kingdom), shows that administrative fines are a cheaper complement of criminal sanctions.

Billiet and Rousseau (2014) suggest that the relationship between monetary and nonmonetary sanctions is in complementary and not alternative terms. (For an empirical analysis performed on microdata regarding penalties applied by courts in Europe, see Billiet et al. 2014.) In

their empirical research, they found that the fines are usually applied together with other criminal sanctions, thus confirming the complementary nature of the different kinds of criminal sanctions.

Billiet and Rousseau (2014) investigated how prison sentences for environmental crime effects are used in fact and their deterrence effects to violators in Flanders, using statistics of seven courts of first instance and the Court of Appeal of Ghent, regarding the complete case law from 2003 to 2007. This empirical analysis confirms that in the EU, countries like Belgium, in 87.49% of criminal proceedings, only a fine sanction was applied to individual violators. These scholars in their interesting study found that the kind of environmental problem does not matter (Billiet and Rousseau 2014) and that prison sentences are not always executed. (Rousseau (2009) performed an interesting empirical analysis of the court sentences in proceedings regarding environmental crime, finding that judges protect the private assets and calculate the sanctions in consideration of the magnitude of the harm).

Almer and Goeschl (2015) performed an empirical analysis on a special kind of environmental crime regarding waste, considering a panel dataset of 44 counties from the German state of Baden-Württemberg between 1995 and 2005. Their outcomes support the theoretical assumption that criminal sanctions have a greater deterrence effect, although the magnitude of this effect depends on the intensity of enforcement. Moreover, the economic conditions and policy measures adopted at jurisdiction level play a significant role to explain why similar law infringements seem to be evaluated and punished in different ways.

The deterrence effect of criminal sanctions to punish the violators of environmental law seems to be a promising field of future research to draw guidelines for further legislative measures.

Environmental Policy: Choice

Donatella Porrini

Department of Management, Economics,
Mathematics and Statistics, University of Salento,
Lecce, Italy

Abstract

The choice between environmental policies is traditionally considered in terms of *ex ante* versus *ex post* interventions on the behavior of (potential) injurers that (can) cause an environmental accident with a consequent environmental damage. Moreover, market-based policies can be implemented as an indirect form of incentive for correct behavior. The two market-based policies, taxes and tradable permits system, are compared on the basis of the difference between price and quantity instruments. And finally, the real situation of the presence of an environmental policy mix is considered as a research challenging topic.

Definition

An environmental policy, on an economic analysis of law point of view, is an instrument to correct malfunctions and subsequent inefficiencies that originate from the presence of market failures: the environment appears as a “public good” that may not be appropriated by anyone and has no market price; the damage to the environment is a case of “externality,” in that it is, fully or partly, a social cost that is not internalized into the accounts of the parties causing it (Cropper and Oates 1992).

Introduction

Different policies can be implemented to reach a given set of environmental protection objectives. But nearly all environmental policies consist of two components: the identification of an overall goal (such as a certain level of air quality or an

upper limit on emission rates) and the choice of instruments to achieve that goal. In practice, these two components are often linked within the political process, because both the selection of a goal and the mechanism for achieving that goal have important political implications.

“But looking at this problem from a law and economics perspective, we can move from the theoretical definition of the efficiency of different instruments to their practical, and so direct, potential to achieve concrete objectives. In particular, three objectives emerge as relevant in judging the practical efficiency of environmental policies: the first is paying accident compensation to the victims; the second is prevention, in the sense of providing incentives for firms to improve safety standards; and the third is connected with technological change in the sense of encouraging firms to adopt lower-risk technologies” (Porrini 2005, pp. 350, 351).

Hereafter, the choice between environmental policies is considered in terms of *ex ante* versus *ex post* interventions on the behavior of (potential) injurers that (can) cause an environmental accident with a consequent environmental damage. Moreover, market-based policies can be implemented as an indirect form of incentive for correct behavior. The two market-based policies, taxes and tradable permits system, are compared on the basis of the difference between price and quantity instruments. And finally, the real situation of the presence of an environmental policy mix is considered as a research challenging topic.

Ex Ante Command-and-Control Policy

Generally, an *ex ante* policy focuses on the potential injurer’s activity from which the damage originates, with effects that precede the occurrence of the same. In the environmental sector, in particular, the standard-setting instrument is most common and consists in the enforcement, by an agency, of a given prevention level in any way that may be quantitatively defined. Practically, this *ex ante* policy is founded on a centralized structure in charge of setting standards and then ensuring their compliance, according to the

so-called classical “command-and-control” process.

As to the US experience with *ex ante* policy, the activity of the EPA (Environmental Protection Agency) provides a clear example of policy of this kind implemented by an independent environmental authority. This agency performs its tasks through the enforcement of polluting emission thresholds and the performance of inspections and, possibly, of actions brought to the federal courts.

The choice to develop this *ex ante* policy provides the advantage of centralized agencies to assure a cost-effective calculation on the basis of the expected damage and of the marginal cost of the different technical preventive instruments. So, following the traditional economic analysis of law approach, well-defined standards generate the correct incentive for the firm to act with caution and take the best production and prevention decisions (Calabresi 1970).

Moreover, in its application, the centralized search facilities, the continual oversight of problems, and a range of regulatory tools make this kind of policy capable of systematically assessing environmental risks and implementing a comprehensive set of instruments. But, on the other hand, as disadvantages, the agencies may not be very flexible in adapting to changing conditions, and a centralized command structure, relying on expert advice, may be subject to political pressure as well as to collusion and capture by the regulated firms.

Summarizing, the choice to implement an *ex ante* command-and-control kind of policy responds to the need of “uniformity versus flexibility.” “To be efficient, such regulations, require information on alternative techniques and a balancing between the profit to the industry and the environmental impacts of various production techniques and processes. Specific production standards may, therefore, rapidly become obsolete” (Faure and Skogh 2003, p. 198).

Ex Post Liability Policy

The most common *ex post* policy consists in a liability system that provides for a legal authority

to identify a party responsible for the damage caused by an environmental accident.

Again, the experience in USA can be considered as an example given that the problem of environmental liability in that country has emerged more than 30 years ago. In fact, in 1980 the Congress issued the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) with the main purpose to bring quick relief and remedy action after an accident, to cope with the “decontamination” of polluted sites, and to recover the cleanup and compensation costs from the liable parties.

The *ex post* policy is based on the system of liability assignment to the polluting company according to the so-called polluter pays principle. Such principle has been defined as “economic” in that it provides for the economic option of charging the cost of the environmental damage to a specific party that is liable for the accident, rather than generally to the society.

A system of liability satisfies the need to compensate affected parties for physical and economic damage originated from a real event loss and to stimulate preventive measures against future accident.

On an economic analysis of law point of view, in a world of perfect (complete) information, this *ex post* policy is an efficient method to solve the problem of internalizing the economic effects of environmental accident. In fact, the firms face the proper incentive to take the optimal level of precaution, and the individuals, harmed by pollution, receive the proper compensation, possibly through an insurance provider.

But in practice, the assignment of individual responsibility shows relevant problems that we can summarize in:

- (i) a specific polluter could in many cases be difficult to identify because some consequences (i.e., a disease or a reduction in health) may be attributed to a number of different factors besides the pollution and, even if a link between a pollutant and the consequences may be established, it could turn out to be difficult to determine the firm responsible for the damage;

- (ii) compulsory insurance contracts that the firms are induced or forced to buy could be incomplete or insufficient because of the difficulty to determine the probability of accident and the distribution of the loss caused by environmental damage, hence making the pricing of the contracts complex;
- (iii) the polluter can in some cases be insolvent and unable to pay for cleanup or compensation costs because of the (small) size of the firms operating in dangerous activities in comparison with the (high) costs and penalties of environmental damage.

A liability system can be applied using either a negligence or a strict liability regime. The law and economic literature compares the two regimes considering how they provide a potential polluter with incentives to take adequate preventive measures (Cooter and Ulen 1988). And, generally, strict liability is preferred in the presence of informational issues (Epstein 1973). This could be the case of environmental accidents, where it is particularly difficult to determine the standard to assign liability on the basis of negligence: in reality, pollution has many sources and (potentially) many victims, and it is a hard task to prescribe efficient pollution standards based on a calculus of the abatement cost and the external harm of every source of pollution.

Ex Ante Versus Ex Post Policies

The traditional economic analysis of law approach compares ex ante and ex post policies on the basis of their role in achieving the efficiency goal to stimulate the socially optimal level of preventive care and in so doing controlling the environmental risk.

The authorities responsible for meeting these objectives are the regulatory agencies, which fix standards and check their compliance, and the courts, which assign liability. "Statutory regulation, unlike tort law, uses agency officials to decide individual cases instead of judges and juries; resolves some generic issues in rulemakings not linked to individual cases, uses nonjudicialized procedures to evaluate technocratic information, affects behavior ex ante

without waiting for harm to occur, and minimizes the inconsistent and unequal coverage arising from individual adjudication. In short, the differences involve who decides, at what time, with what information, under what procedures, and with what scope" (Rose-Ackerman 1991).

A seminal contribution by Shavell (1984) presents four determinants on the basis of which comparing the two different policy systems.

The first determinant is the difference in information between private parties and the regulatory authority. It clearly could happen that the nature of the activities carried out by the firms is such that the private parties have better knowledge about the cost of preventive care and of the risks involved. In such a case, a liability system is more efficient because it makes the private parties the residual claimants of the control of risks. But it may also happen that the regulator has better knowledge because of the possibility of centralizing information and decisions, in particular when knowledge of risks requires special replicable and reusable expertise. In such a case, direct regulation is likely to be more efficient.

A second determinant is the limited capacity of private parties to pay the full costs of an accident, either because of limited liability or of insufficient assets; this is the case called "judgment proof" (Shavell 1986). An ex post liability policy allows to reach a social optimal solution, only if the private parties can finally cover the damage in the dimension decided by the court. In all the cases in which the damage is superior to the resources of the private parties, a liability system does not provide private parties with proper incentives for preventive care. So the greater the probability or the severity of an accident are and the smaller the assets of the firm are (relative to the potential damages), then the greater the efficiency of ex ante regulation.

The third determinant is the probability with which the responsible parties would face a legal suit for harm caused. This problem is particularly present in environmental risks: in many cases the victims are widely dispersed with none of them motivated to initiate a legal action, harm may appear only after a long delay, and specifically responsible polluters may be difficult to identify.

In the comparison with *ex ante* policy, *ex post* liability is more uncertain and so less efficient.

The fourth determinant is connected with the general level of administrative expenses incurred by the private parties and the public. The cost of a liability system includes the cost of legal procedure and the public spending for maintaining legal institutions. The cost of an *ex ante* policy includes the private costs of compliance and the public spending for maintaining the regulatory agencies. In this case the advantage of the liability system is that legal costs are sustained only if a suit occurs, and, if the system works well, stimulating the efficient level of prevention, the number of suits will decrease, and therefore the costs are becoming lower in time. On the other hand, under an *ex ante* policy, the administrative costs are sustained whether or not the accident occurs because the process of regulation is costly by itself, and the regulator needs in any case to collect continually information about the parties, their activities, and the risks.

Summarizing, *ex ante* policy is better when harm is large, is spread among many victims or, takes a long time to show up, when accidents are not very rare events, and when standards or requirements are easy to find and control.

In another contribution, Kolstad et al. (1990) support the hypothesis of the complementarity between *ex ante* and *ex post* policies because, even if the economic literature has mainly studied separately the two systems, characterizing each of them by different inefficiencies, the phenomenon of joint use of *ex ante* and *ex post* systems is widespread.

Among the determinants presented by Shavell (1984) and above analyzed on the basis of which comparing the two different regulatory systems, the authors concentrate on the fact that potential injurer is in many circumstances uncertain about whether a court will hold him liable in the event of accident and subsequent suit. But an *ex ante* regulatory system can correct this inefficiency, at least in part.

The development in the contributions within the economic analysis of law literature shows an increasing attention to the relationship between *ex ante* and *ex post* policies characterized by

imperfections in their implementation, as complements or substitutes, both in providing the incentives to the optimal level of preventive care. So the debate about policy choice mainly focuses on the achievement of a given target in terms of efficiency in a framework where imperfections are considered as reasons to prefer one policy to the other.

Market-Based Policies: Taxes and Tradable Permits

Within the category of market-based instruments, there are policies that encourage behavior through market signals rather than through explicit directives to firms. So, in practice, rather than imposing uniform emission standards, market-based instruments introduce a cost for the firm in the form of a tax or of the price for a permit, leaving then the firms to deal with the problem to control and limit the pollution level on the base of their marginal costs.

So stressing an efficiency kind of argument, in the case of the implementation of market-based instruments, each firm determines until which level it is more convenient to reduce pollution given the possibility to pay a tax or to buy a polluting permit.

The two most important features of market-based instruments with regard to traditional command-and-control approach are cost-effectiveness and dynamic incentives for technology innovation and diffusion. On one hand, command-and-control policies, to set standards, require that policy makers obtain detailed information about the compliance costs, each firm faces the problem that such information may be not available to government; by contrast, market-based instruments provide for a cost-effective allocation of the environment control burden without the need for this information.

As market-based policies, the most common are tradable permits system and environmental taxes.

A system of tradable permits is based on the allocation of a number of permits to the firms, each of them allowing the emission of a given amount of a pollutant; if the facility is able to

reduce its emissions (preferably through the use of less polluting technologies), it can sell its remaining emission permits to other firms that are unable to meet their quotas.

It is clear that the advantage of this policy is the possibility to fix the level of pollution control and in the case of technological change, without additional government intervention, to freeze this level.

On the other hand, a policy based on taxation attributes a price on polluting activities that will be incorporated by the firm in the price of the products. In this case the incentive for the adoption of abatement techniques relies on the market mechanism because if a firm does not apply the optimal techniques, it will pay more taxes and sell its products at a higher price than other firms with negative effects in terms of competition.

Market-based instruments, as regulatory devices that shape behavior through market signals rather than explicit instructions on pollution control levels or methods, are often described as “harnessing market forces” because they can encourage firms and individuals to undertake actions that serve both their own financial interest and public policy goals (Stavins 1998).

Environmental taxes and tradable permits system are both market-based policy instruments, but their implementation is different: taxes fix the marginal cost for carbon emissions and allow quantities emitted to adjust, whereas tradable permits fix the total amount of carbon emissions and allow price level to change according to market forces. Because of these differences, the former are defined as “price” instruments for the correlated effect to increase the price of certain goods and services, thereby decreasing the quantity demanded, while tradable permits are defined as “quantity” instruments for the feature to directly fix the quantity through the number of permits.

The literature on environmental policy choice describes alternative instrument taxes as price control instruments and tradable permits as quantity control ones, and many contributions compare their relative performance in terms of efficiency under uncertainty.

The starting seminal article of Weitzman (1974) analyzed the optimal instrument choice under a static partial equilibrium framework,

consisting of a reduced form specification of costs and benefits from abatement. In the setup, an agency issues either a single price order (fixed price) or a single quantity order (fixed quantity), and these fixed policies result in different expected social welfare outcomes under uncertainty. Specifically, Weitzman shows that, with imperfect information about the abatement costs, the relative slopes of the marginal benefit (damage) function and the marginal cost function determine whether one instrument is preferred to another. If the expected marginal benefit function from reducing emissions is flatter than the marginal cost of abatement, then a price control is preferred. If, however, the marginal benefit function is steeper, then a quantity control is preferred.

In the law and economic literature, Kaplow and Shavell (2002) deal with the standard context of a single firm producing externality; moreover, they consider the case of nonlinear corrective tax, and multiple firms jointly create an externality, demonstrating the superiority of taxes to permits.

Despite the results of the majority of contributions that a taxation system is preferable to tradable permits system in terms of economic efficiency, this policy obviously faces political opposition. On the supply side of the market, companies oppose taxes, as a cost that implies a revenue transfer to the government and also as a factor that can imply negative effect on competition in an international context; on the demand side, consumers are typically not happy and pay at the end a higher price on the products, and environmental groups oppose taxes because, unlike tradable permits system, these fail to guarantee a particular reduction in the emission level.

Conclusive Remarks About the Mix of Policy Instruments

We have analyzed the different policies as alternative instruments that can be implemented to reach given environmental objectives considering, on a law and economic perspective, their different degree of efficiency.

But environmental policy instruments usually operate as part of a “mix” of instruments, and in

practice several different policies are applied to address a given environmental problem as broadly as possible with the target to cover all sources of pollution in every relevant sector of the economy.

The efficiency of these mixes can be enhanced by adhering to many of the same principles that guide the use of individual instruments and by explicitly considering the way in which different instruments interact.

For example, one possible mix could be tradable permits together with tax system.

On an efficiency point of view, while a policy based on “quantity,” such as a tradable permits system, can provide a degree of certainty as to the environmental outcome, the compliance costs that will eventually be faced by polluters are likely to be quite uncertain under these systems. But this uncertainty can be reduced by introducing a tax system as a “safety valve” in the permit price. In effect, this allows polluters to emit whatever amount they like, in return for paying a fixed price, the “tax,” for any emissions for which they do not hold an allowance, should the permit price exceed a predefined level.

This mix between environmental policies presents some economic advantages that are key motivating forces to try to develop research on this topic.

First of all, policy mix allows for exchanges across different systems and thereby facilitates cost-effectiveness, that is, achievement of the lowest-cost emission reductions across the set of linked systems, minimizing the overall cost of meeting the collective cap.

Mixed systems may also provide regulatory stability as an advantage for affected firms, in the sense that it may be more difficult to introduce changes in an emission-reduction scheme when those changes require some sort of coordination with other policies (Johnstone 2003).

There are also administrative benefits from the mix that come from sharing knowledge about the design and operation of different policies to find the best practice, but also from the reduction of administrative costs through the sharing of such costs and the avoidance of duplicative services.

Despite the just mentioned economic advantages, we cannot find in the law and economic literature until now so many researches that

develop theoretical models based on the mixed use of different environmental policy instruments that are still considered mainly as alternative.

Equilibrium Theory

Pasquale L. Scandizzo

CEIS (Centre for International Economic Studies), University of Rome “Tor Vergata”, Rome, Italy

Abstract

Equilibrium is a key concept of modern science, from classical mechanics to biology, so

that its importance for economics should not be a surprise. More surprising is perhaps its central role in the tentative transition of economics from an essentially institutional set of disciplines to a unified branch of modern science, based on a rigorously axiomatic system. The main attempt for such a transition, which has as protagonists several Nobel prizes, was consumed in the 1950s, in an atmosphere first of elation and then of disillusion that appears very similar to that experienced 20 years earlier by mathematicians because of the failure of the Hilbert unification program. In spite of the somewhat spectacular nature of both successes and failures of its mathematical theory, however, general equilibrium has a central role in the history of modern economics that goes much beyond its formal treatment. This role is inextricably related to the notion of the market and is perhaps the primary constituents of the eclectic nature and vitality of contemporary economics.

General Equilibrium as a Property of the Market

Perhaps because of its increasing importance to the modern economy, the concept of market equilibrium has been evolving over the course of the story, so as to embrace different categories, in some cases more inclusive and in others more specific, which extend over the entire arc of economic phenomena. This extension of a concept originally defined in a very simple fashion has led to considerable confusion, especially since the theory and practice of modern economic systems are, in fact, completely dependent on market equilibrium as a category of the spirit, even more than as a theoretical model.

What then is a market equilibrium and in what sense can it be defined as a “general equilibrium”? The word market was born as the past participle of the Latin verb *mercari*, which means trading, and designates the beginning of its use of a physical place where the goods available for exchange were exposed and where, therefore, negotiations and exchanges were carried out. The designation

of the place, still widely used in everyday language, came to denote at the same time the space, the exchange, and the agents engaged in trade of specific goods. As a result, the place evoked by the term became increasingly virtual, the transition between the material and the virtual occurring through the discovery of the properties of the markets that extend well beyond their apparent spatial limits and culminate in the concept of market equilibrium. Equilibrium, on the other hand, was a concept that only gradually came to characterize the market, as its assertion went hand in hand with the increasing virtuality of the exchange and the agents involved in making it happen.

The process by which the market became dematerialized, in fact, can be seen as an increasing perception of its role as a mechanism to balance the exchange, by ensuring that agents meet and act appropriately to achieve a balance of actions and desires. For example, one of the precursors of economic liberalism Richard Cantillon (1755) offers a description of the market and its reasons to demonstrate how the activity originating from the establishment of a periodical fair creates broader consequences:

There are some villages where markets have been established by the interest of some proprietor or gentleman at court. These markets, held once or twice a week, encourage several little undertakers and merchants to set themselves up there. They buy in the market the products brought from the surrounding villages in order to carry them to the large towns for sale. In the large towns they exchange them for iron, salt, sugar and other merchandise which they sell on market days to the villagers. Many small artisans also, like locksmiths, cabinet makers and others, settle down for the service of the villagers who have none in their villages, and at length these villages become market towns. A market town being placed in the centre of the villages, and at length these villages become market towns. A market town being placed in the centre of the villages whose people come to market, it is more natural and easy that the villagers should bring their products thither for sale on market days and buy the articles they need, than that the merchants and factors should transport them to the villages in exchange for their products. (1) For the merchants to go round the villages would unnecessarily increase the cost of carriage. (2) The merchants would perhaps be obliged to go to several villages

before finding the quality and quantity of produce which they wished to buy. (3) The villagers would generally be in their fields when the merchants arrived and not knowing what produce these needed would have nothing prepared and fit for sale. (4) It would be almost impossible to fix the price of the produce and the merchandise in the villages, between the merchants and the villagers. In one village the merchant would refuse the price asked for produce, hoping to find it cheaper in another village, and the villager would refuse the price offered for his merchandise in the hope that another merchant would come along and take it on better terms. (Cantillon 1755)

For Adam Smith, one of the founders of the notion of equilibrium, the market was also originally identified in a physical space, such as a place dedicated to trade in the city or even the entire city (as a market town) with respect to the surrounding countryside. For him, however, the essential feature of the market was its ability to feed and be fed by the division of labor. In this sense, the market becomes a place dedicated to the determination of value by a threefold change: (a) from primitive societies to modern societies, (b) from the family to the firm, and (c) from the countryside to the cities. Smith's conception of the market is therefore first and foremost ideological, as pointed out by Joan Robinson (1962). It identifies the transition between two ideal states "the economy of barter" and "the market economy," as a form of substantial progress that is the basis of value creation and prosperity of modern societies. In this sense, Smith sees the market as an anthropological construct, which explains the redemption of man from the "rough state" where the assets and exchanges are both limited by the absence of the division of labor.

Ricardo, who starts from the paradigm of the Smithian division of labor to develop his fundamental theory of comparative advantage, seems to show a total nonchalance towards the concept of the market as compared to that of equilibrium. The market as such is evoked only from time to time, as a place dedicated to trade, in which the goods produced are carried. However, in the great debate on international trade, it remains a kind of constituency space, which distinguishes the "foreign" from the "home" market, both defined almost as a side effect of trade between countries. In fact,

both Smith and Ricardo did not seem to attach much importance to the market, in the sense that they take its presence for granted within a system that they characterize more than as a "market economy," as an economy of capital. Yet the fundamental problem, in this system, is not to explain the nature and behavior of economic entities, but rather to solve the problem of achieving equilibrium through the formation of value and the distribution of wealth.

[...] On the contrary, as the rise in the real value of silver, in consequence of lowering the money price of corn, lowers somewhat the money price of all other commodities, it gives the industry of the country where it takes place, some advantage in all foreign markets, and thereby tends to encourage and increase that industry. But the extent of the home market for corn must be in proportion to the general industry of the country where it grows, or to the number of those who produce something else, to give in exchange for corn. But in every country the home market, as it is the nearest and most convenient, so is it likewise the greatest and most important market for corn. That rise in the real value of silver, therefore, which is the effect of lowering the average money price of corn, tends to enlarge the greatest and most important market for corn, and thereby to encourage, instead of discouraging, its growth. (Ricardo 1821, Chapter 24, p. 42)

Walras was to argue, with the *esprit de finesse* of his national tradition, that the market was not a single place, but a system of interdependent markets, and therefore, interdependence was its constitutive principle which also linked the participants. From the subjective point of view, the market consisted then of entrepreneurs, brokers, and owners of factors of production (workers, capitalists, and rentiers) connected with each other and with the goods exchanged by a mechanism (the *tâtonnement*) search of equilibrium prices. Walras does propose a unique identification of entrepreneurs, not so much because, according to his theory, they maximize their utility through the pursuit of maximum profit, but because they are characterized as intermediaries between the markets for factors of production and that of the goods. Under equilibrium conditions of production, the entrepreneur does not get either profits or losses (Walras 1877b, p. 232, 1954, p. 225). But equilibrium, for Walras, is actually

a theoretical notion that characterizes the market: it constitutes the normal state to which all variables tend perpetually and automatically in a competitive free economy (Walras 1954, p. 224). Since it contains implicitly the equilibrium of exchange, the market owns the further property of equality between the supply and demand for final and intermediate goods, as well as factors of production.

After Walras, it was Marshall who addressed more explicitly the problem of equilibrium, by characterizing the market as a meeting place of supply and demand. Although based on the comparison of “needs” or “desires” (wants), rather than the incipient neoclassical paradigms (demand, supply, perfect competition), this concept was somewhat overshadowed by the theories of trade in Smith and Ricardo. It needed, however, to be made explicit and descriptive, to accommodate the concept of price formation, bargaining power, and competition. In Book V of his *Principles of Economics*, Marshall begins by tracing a continuum of markets, wider or narrower depending on the position between the two extremes of easily transferable products from open markets and relatively immobile products captured by closed markets:

Thus at the one extreme are world markets in which competition acts directly from all parts of the globe; and at the other those secluded markets in which all direct competition from afar is shut out, though indirect and transmitted competition may make itself felt even in these; and about midway between these extremes lie the great majority of the markets which the economist and the business man have to study. (Marshall, *Principia*, Libro V, Cap. I)

In this continuum, the unique characteristic of markets is that they allow economic agents to find a balance between desires and efforts. The easiest way to find this balance, says Marshall, tracing in this way the classical phylogeny, is to a person who gets what she wants directly from her work. A second tool is the barter, but both of these mean being primitive and limited in their practical consequences; in the end, the emergence of the market appears to be a sheer necessity.

In the market two quantities are compared, subject to variation: the supply price, given by

the minimum price that the agent who proposes the sale is willing to accept for the goods offered, and the bid price, which is the maximum price that the agent who contemplates the purchase is willing to pay. Generally, if the goods are divisible, there are no particular problems in finding the equilibrium point, i.e., the quantity of goods exchanged for which the bid price and the supply price match. There are, however, particular markets where the achievement of this point is not trivial: the labor market, for example, is characterized by the fact that for anyone who offers the sale, only one unit has to be put on the market and may be in need, so that the worker may be willing to accept a very low salary. Her supply price, determined on the basis of the cost of her effort, may not coincide with the price for which she is forced to sell her work to survive.

Marshall's treatment is striking for its clarity but also, as in the case of the classics, for the essentially passive nature attributed to the market. The latter, in addition to be configured as the virtual space of the exchanges, i.e., as a locus operandi with desirable characters of full information, competitiveness, and so on, does not appear to have in any way a coordinating role. The coordination of trade is in fact an automatic consequence of the comparison between supply and demand (or, through the supply price and the bid price, the comparison between effort and desire) and does not even need to resort to the Walrasian auctioneer. In fact, the very concepts of demand and supply prices appear as abstractions, raising the question of balance in an essential way, and can be considered the disembodied protagonists that allow to bypass a theory of the functioning of the market. This is perhaps also due to the fact that, as noted by Colander (1995), Marshall was aware of a higher complexity of the general equilibrium problem and that his conception was more subtle and pervasive than Walras, combining the ideas of multimarket coordination and equilibrium “generality” with those of dynamic adjustment and coordination from a plurality of institutions. While the Walras model is addressed to the solution of a multiple matching problem between goods supplied and goods demanded in an interdependent perspective, Marshall

conceives general equilibrium as a process with “chaotic” characteristics. This process arises from the fact that preferences are constantly updated and economic agents strive to find the equilibrium again and again by moving along “corridors” of coordination which are contingent on the existence and operability of institutions.

A little less than a century later, in a text characterized by the almost total absence of the word “market,” Thorstein Veblen constructs a theory of the entrepreneur, based on the idea that general equilibrium is a dynamic process, depending on the figure of the “captain of industry,” motivated by the opportunities provided by the market to acquire a monopoly position in a economy dominated by machines and processes of product standardization.

Veblen’s model of the “captain of industry,” dear to the frontier capitalism, has the reference specimen of big businessmen, such as the railway investors, whose fortunes, however, consisted not only in the vision and passion for the gains but also in the ability to fight with success against other entrepreneurs and, on the side of consumers, seize the best opportunities for emerging markets. To indicate the wisdom of this opportunistic attitude, Veblen cites, in particular, the saying “charging what the traffic can bear” (Veblen 1904, Chapter 3), which refers to the nascent industry of American Railroads – a service rather than an industry – but characterized by the use of powerful machines.

The market and with it the very notion of equilibrium thus tend to disappear in a heroic perspective of entrepreneurship. Veblen anticipates what will be the central observation of Coase and the starting point of the neo-institutional economics, which identifies the company as an alternative to the market and its command and control structure as an alternative to the impersonal balance between demand and supply. Physiocrats, classical and neo-classical economists, and, in their specificity, even the members of the Austrian school, from Mengel to Böhm-Bawerk, in fact, consider the entrepreneur and the enterprise an integral part of the market, as opposed to the family economy and the model of consumption. In Veblen, however, the idea of a self-governing equilibrium reappears in the role

of the captains of industry as of those who, fighting with other entrepreneurs, to eliminate them from the market, achieve equilibrium by freeing the economy from an excess of management, because “[...] it appears that the greater the amount of pecuniary management, the smaller are the services provided to the community.”

The heroic function of the entrepreneur for Veblen coincides with a form of competition that seeks the disequilibrium and is therefore completely different from that of Walras and Marshall. The experience of American capitalism will inspire 20 years later Max Weber, in attributing a role equally dynamic and heroically ascetic to the moral entrepreneur created by the Protestant Reformation. It is interesting to contrast the points of view of these two authors, Veblen, an economist with sociological propensities, and Weber, a sociologist with inclinations as an economist, because they derive a heroic role for the entrepreneur from completely different views of his moral and creative features. For Veblen, the entrepreneur is spurred by the profit motive and the desire to amass a fortune. The drive towards these goals has its social utility, but to pursue them effectively, the entrepreneur must be substantially amoral and essentially disruptive. For Weber, on the contrary, the success of the capitalist entrepreneur embeds, through the Protestant ethic, moral character and a social quality dramatically higher for the market before birth and consolidation of the reformed religion.

More recently, Kirzner, the most influential living economist of the Austrian school, takes up the theme of the Socratic role of the entrepreneur, making him, however, the principal agent of the search for market equilibrium. According to Kirzner (1973), the function of the entrepreneur as an innovator gives impetus, through her tireless spirit of initiative, to the entire economy. In doing so, the entrepreneur plays a crucial role in correcting market failures, through the activities of arbitrage and speculation. In the process of finding and reaching, the entrepreneur achieves general equilibrium in a far broader sense, as balance, dynamics, and completeness of the markets. In addition, speculative activities, often held to blame, cause substantial benefits for

consumers, because they eliminate the rents due to disequilibrium and push the market towards more efficient conditions. For the entrepreneur to be able to fully release her energy in a beneficial way, it is necessary that the institutional environment is suitable, and entrepreneurial initiative is not mortified by the “traps and snares” of bureaucracy and regulation.

The entrepreneur is therefore the keystone of the economic system because she keeps alive the work, as in the heroic vision of Veblen and Weber, and at the same time, through her constant pursuit of profit, ensures that market activity goes to fruition. As an innovator, Kirzner (1989) argues that the entrepreneur also operates ethically even when she captures high incomes and excess profits. These are in fact the result of the fact that she has discovered the use of resources, thus making to come to life (economic) economic goods that did not exist before. As a beneficiary of distributive justice that rewards merit, the entrepreneur is therefore a fully consistent moral subject.

In the face of these attempts to explain the historical and institutional market, the long wave of the neoclassical school, which is rooted in the principle of specialization and cooperation, reemerges with great force. Wicksteed is perhaps the economist who argues more persuasively, without the use of mathematics, the paradigm and the marginalist theory of equilibrium which will become the core of the so-called neoclassical synthesis. His Presidential Address (1914) contains a concise summary of the marginalist theory of value and distribution and, at the same time, offers an incisive way in the implications of this theory for the nature of the institutions. First of all, the economy is based on a principle of cooperation: “The economic body [...] of an industrial society is an instrumentality for which each man, doing what he can for some of his peers, he gets what he wants from others”. Secondly, the principle of maximization does not imply global complex calculations, but only a comparison algorithm of local differences:

[...] which means, in common parlance, that what an individual will be willing to give something in return, but be rather lacking, is determined by comparison of the difference that he thinks that its

possession would do for him except that he would give anything in return would cause [...].

Moreover, it is this principle of equality of differences that explains both the balance of the individual and that of the market, i.e., between individuals, in the sense that as long as someone believes that an act of exchange may reduce the gap between two opposing differences, he will attempt to make the exchange [...].

What Is General Equilibrium?

Because of its intrinsic complexity and its very diverse history and in spite of its centrality in economic theory, the notion of general equilibrium that has gradually achieved consensus is both subtle and controversial and still subject to alternative interpretations by different scholars. The point of departure concerns the more general notion of “equilibrium,” where, since the physiocrats, the main governing idea is the objective property of a material “balance” between demand and supply of both goods and services. It is this balance, which is surprisingly attained by exchange through unknown and somewhat mysterious means (e.g., Smith’s “invisible hand”), that ensures that the economy is not clogged with unwanted stocks of commodities or plagued by involuntary unemployment or lack of goods or services needed or desired. Material balance generates the further idea that a second, essential property of equilibrium has a subjective nature: in equilibrium agents are content in the sense they feel themselves in a desirable state of balance, because they sell what they want to sell and buy what they want to buy at mutually agreeable rates of exchange. This subjective condition in turn leads to stipulate that in equilibrium agents realize their plans and are satisfied because they behave according to what they believe is right to pursue their objectives and have no need or desire to change.

So far the notion of equilibrium described does not have any special connotation as partial or general, but simply characterizes a condition where things are at rest, in the sense that there is no incentive to change the position of any agent,

either to reduce objective costs or to increase subjective satisfaction, unless underlying exogenous conditions change. In this context, the “partial” equilibrium model emerges from a desire to simplify the analysis of price formation, limiting the interaction between demand and supply and the role of prices to one market or to a subset of interdependent markets. Partial equilibrium, therefore, does not mean that the multiplicity of markets is necessarily ignored nor that any of the properties of equilibrium (material balance, subjective self-fulfilling plans) are discarded but only that one part of the economy is considered exogenous. More specifically, partial equilibrium generally ignores the linkage between price determination and income formation, as well as the wealth effect caused by the fact that the increase or decrease in prices changes the value of agents’ endowment of economic resources.

A further, often tacit, characterization of market equilibrium is that it is “competitive,” i.e., it arises in a market where there is a plurality of agents, each too small to determine, through her individual behavior, the outcomes of the exchange. Of course, monopolistic equilibrium has been cultivated as a theoretical field by several scholars, but it is typically the solution of a noncooperative game and does not possess the combination of objective (material balance) and subjective characteristics of competitive equilibria. As John Nash (1950, 1951) demonstrated, in fact, the notion of subjective equilibrium does not go hand in hand with the accomplishment of material balance. In the theory of noncooperative games, a Nash equilibrium is reached if each player maximizes her objective function under the full knowledge of the strategies of the other players. In such an equilibrium, a higher level of mutual rest is reached in that no player may benefit by changing her strategy if no other player does so. This does not mean, however, that players would not like to change the allocation of goods or services characterizing the equilibrium. In most cases they would, but they cannot, because such an allocation is determined by a higher-level equilibrium among the strategies leading to the allocation. A Nash equilibrium is thus a meta-equilibrium, and while a competitive

market equilibrium qualifies as a Nash equilibrium, a Nash equilibrium is not necessarily a competitive equilibrium and does not necessarily require material balances between demand and supply or agents’ contentment about the allocations realized by the enactment of their strategies.

What is then “general equilibrium”? One is tempted to reply that general equilibrium describes a condition where all markets are in equilibrium, both in the sense that all markets are cleared (demand equals supply) and all agents fulfill their plans. However, while this definition certainly appears simple and direct, it is not complete, since general equilibrium, unlike partial equilibrium, in addition to material balances and subjective fulfillment requires that the distribution of wealth is consistent with resource allocation. General equilibrium theory, in fact, concerns three different circles of causation: (i) between demand and supply of goods and services on one hand and prices and incomes on the other, (ii) between the formation of incomes from demand and supply of factors of production and their prices, and (iii) between the initial resource endowment and the redistribution caused by productive choices and institutional transfers. The precise way in which these three circles interact was not clear until in relatively late times, R. Stone and A. Brown (1962) formalized it in the so-called social accounting matrix (SAM). The focus on the proof of the existence by the celebrated Nobel Prize-winning economists Kenneth Arrow and Gerald Debreu, furthermore, while in itself a benchmark of economic theory, for a long time diverted the attention of the scientific community from more practical features of general equilibrium, such as its computability under alternative scenarios of competition and information and its use for planning and project evaluation. Computable general equilibrium (CGE) models, mainly developed as a result of research efforts at the World Bank in the 1970s, were thus mainly a spin-off of the application of SAM and even in their advanced, present-day form, they tend to evoke the initial dualism between a core set of social accounts and a complementary and highly variable set of behavioral and technical equations.

While at first it may not even be seen as the same subject, since the beginning of its being theorized, the outcome of general equilibrium has been identified with efficiency, in the sense that a fully competitive price system brings about more efficient outcomes than any other practical arrangement or planning mechanism. The linkage between competitive equilibrium and efficiency was formalized by Pareto (1909) and Bergson (1938) and, in its most advanced form, by Arrow (1951) and Debreu (1951) in the form of a full equivalence theorem. Pareto's definition – exemplar in its efficacy – characterizes efficiency as a feasible allocation, i.e., the choice of feasible sets of goods to consume and to produce on the part of the economic agents, that cannot be changed without making at least one agent worse off. Efficiency thus simply implies that it is not possible to modify an efficient allocation without damaging someone. It is the expression of the social trade-off that arises once all possible improvements with no impact on distribution have been made.

Two basic theorems of welfare economics link Pareto efficiency to the notion of general (Walrasian) equilibrium. The first says simply that any general equilibrium is Pareto efficient (Arrow 1951; Debreu 1951), while the second theorem states that under certain, rather general, conditions, given a Pareto-efficient allocation, it is possible to find a corresponding general equilibrium and, in particular, a supporting price vector. These two theorems have important policy implications, because they suggest that Pareto efficiency may be obtained either through a decentralized market system (as in the Walrasian model), by letting prices be freely determined by the exchange mechanism, or as a planned allocation, by imposing a system of prices that will support it.

The relationship between Pareto efficiency and general equilibrium foreshadows the question of its existence, which was taken up by Arrow and Debreu (1954), as well as McKenzie (1959) in a series of celebrated contributions. Their work, although focused on a rather narrow subproblem, essentially proved that under certain conditions aggregate demand and supply could be equated

by a set of nonnegative prices. This was a nontrivial result that was contingent on a series of rather restrictive assumptions but was obtained through a mathematical powerful and unifying instrument (the fixed-point theorem) that was in itself shining for originality and simplicity. The result had two drawbacks, however. First, it did not cover nor it proved to be a feasible base for finding circumstances under which the equilibrium was unique. Second, as proved in a series of important and somewhat astounding later contributions by Sonnenschein (1972, 1973), Debreu (1974) himself, and Mantel (1974), the base of the existence proof was a construct, named “the aggregate excess demand function,” which, although resulting from the aggregation of individual demand and supply, was not bound by the limitations deriving from the postulates of rationality. In what has been called “the everything goes” conclusion, in fact, it was proved that such a function, even though the result of individual rational behavior, is not characterized by any special mathematical property. Thus, the existence of general equilibrium seemed to be quite independent of its “micro-foundations,” as a consequence of an essential weakness of the microeconomic “rationality” assumptions, which were proved to be not sufficiently discriminating to impose anything resembling rationality on aggregate behavior.

General equilibrium theory, however, was not devoid of consequences for applied economics. In a series of important research attempts, in large part conducted at the World Bank, several generations of computable general equilibrium (CGE) models were developed and gradually became an important and useful tool for policy analysis. In these models, social accounting matrices (SAM) became the core of the representation of general equilibrium as a circular flow of production, consumption, and incomes, with prices in all markets as the equilibrating variables. Solving algorithm started with fixed-point (Scarf and Hansen 1973) and mathematical programming procedures (Norton and Scandizzo 1981; Walbroeck and Ginsburg, 1981) and gradually developed into nonlinear equation systems and local or global search solution methods (Devarajan et al. 1997). At present, while the macroeconomic models

prevailing in the 1970s have all but disappeared from the economic practice, CGE models are increasingly used around the world, in both their static and dynamic versions, as tools to analyze economic policy options.

Conclusions

General equilibrium has accompanied the development of economic theory both as a founding concept and as a scientific challenge. Its classical version interprets the market as being characterized by a search for coherence, fulfillment, and balance, from the point of view of both the agents and the goods and services traded. In this interpretation, the historical notion of the market as a place in space and time is progressively changed into that of a virtual space, whose prevalent feature is to harbor the dynamism rather than the locus of exchange. The neoclassical view continues this process of dematerialization of the market and pushes it further by focusing on the abstract nature of equilibrium as a mathematical construct and on its existence and uniqueness properties. The ambition of this second approach, which permeates the founding phase of mathematical economics, is to unify economic theory by providing a general and rigorous connection between microeconomic and aggregate behavior.

While successful in imposing a method of theoretical investigation that remains one of the assets of modern economic theory, the neoclassical program did not go beyond proving a theorem of existence of general equilibrium and of seemingly important but somewhat rarified properties of socially efficient allocations. Embarrassingly, the program also proved the micro-foundation illusory, as a consequence of an intrinsic incapacity of the rationality assumptions to characterize aggregate behavior. Surprisingly, general equilibrium theorizing has been instead more successful in applied economics, by providing, through the social accounting matrix (SAM) and computable general equilibrium (CGE) models, an apparatus of sufficient rigor and sophistication to systematize data collection and frame the analysis of complex economic policies.

Essential Facilities Doctrine

Frédéric Marty
CNRS - UMR 7321 Gredeg, Université Côte d'Azur, Université Nice Sophia Antipolis, Valbonne, France

Definition

The essential facility doctrine is a disputed concept in the field of competition law enforcement. According to this doctrine while a dominant operator controls an asset that its competitors cannot bypass to access the market because of its natural monopoly situation or because the unreasonableness of its replication in financial or in technical terms, it may be bound to provide them an access in fair, reasonable, and non-discriminatory terms. This approach may lead to far reaching remedies and is all the more challenged that it is also implemented to intangible assets.

Introduction

The essential facilities doctrine (hereafter the EFD) stems from the notion of market failure and, even more specifically, from the concept

of natural monopoly. The EFD may be used in a situation in which an economic operator access to the market exclusively depends on the decision of a facility owner without any available alternative. The facility owner may be one of its competitors in the downstream market or a market player who controls an infrastructure which plays as a bottleneck to enter the market. The facility at stake can be an infrastructure, an upstream product or service, or an intangible asset. In other words, the facility owner can be a network operator, an upstream monopolist, or a patent holder. The EFD may be activated within the scope of competition law if this upstream monopolist's refusal to grant an access can be qualified as an exclusionary or an exploitative abuse. It can also be used within the scope of antitrust law, at least in principle, if this refusal participates to a strategy aiming at monopolizing a downstream market.

The denial of access may be an absolute one – it is a clear cut refusal to deal – or a “relative” one. In such a case, the access is still possible but the facility owner imposes unfair or discriminatory conditions in terms of access charges or provides to its downstream competitors an access characterized by deteriorated technical conditions that impair the quality of the service provided to the final user. Such an altered access distorts competition.

The first situation may be commonly observed in deregulated industries. A former State-owned vertically integrated firm, controlling a natural monopoly segment (as the local loop in a telecommunication network, the transportation infrastructure in gas or electricity sector. . .) may impose excessive access charges to its new competitors in the downstream market. Margin squeeze strategies may be at stake in such situations. They may consist in imposing an excessive price for the upstream service and in charging an exclusionary price for the downstream one. Cases as *Deutsche Telekom* (case 37.451, European Commission, 21 May 2003) illustrate this type of strategy, implemented in this instance to impair the access to the market of new competitors (ADSL Internet access providers). The incumbent leverages its dominant position to downstream

competitive markets thought cross subsidizations or by raising its rival costs. Imposing excessive access prices may also be a way to accumulate profit margins to finance exclusionary prices in an associated market in a diversification strategy.

The second situation, characterized by voluntary and artificially degraded technical conditions of access, may be embodied by the *Trinko v. Verizon* decision of the US Supreme Court (540 U.S. 398, 2004). In this case, the incumbent, who controls the essential facility, artificially deteriorated the quality of the service provided to final users by its downstream competitor (here AT&T). In other words, its competitor cannot guarantee to its users the same quality service than the one the incumbent provides to its own customers on the downstream market. The access was not denied but the competition on the merits was structurally distorted.

We first consider the implementation of the EFD to network infrastructures in the USA, before analyzing in a second part its use in the EU context, both for tangible and intangible assets. Our third part opens a discussion.

No Man Is a Prophet in His Own Country: The EFD Under Intense Criticisms from US Scholars

The EFD was initially implemented while a “natural monopoly” infrastructure is at stake. Firstly, we assess to what extent this doctrine may be activated in network industries to impose a mandatory access in fair, reasonable, and not discriminatory conditions to the benefit of the downstream competitors of a vertically integrated former monopoly. Secondly, we consider the distinction between the cases of competition laws and of sector-specific regulations. Its implementation as a regulatory tool in the United States contrasts with the situation in the field of antitrust laws. While the concept was crafted within the scope of the Sherman Act enforcement, its activation within the scope of antitrust laws is increasingly challenged.

Reluctances to Implement the Concept in the Legal Sphere

The EFD was crafted in the field of network industries in the USA in the early twentieth

century. Its first use was related to the natural monopoly issue. As a competition through the infrastructures is technically impossible (or collectively suboptimal in terms of welfare), it is necessary to make possible a competition through the services. It supposes to guarantee a fair, undistorted, and equal access to the natural monopoly to any competitor wanting proposing its services to the final consumers, in the downstream market, in which the competition is possible. The most archetypal implementation of this approach was performed in the 1980s in the telecommunications sector with the AT&T decision.

Promoting a downstream services-based competition despite the existence of an upstream monopolistic bottleneck both implies network open access architecture and a regulation that ensures the effectiveness of a *level playing field*. The 1982 US Department of Justice consent decree in the AT&T case embodied such a logic (United States District Court of the District of Columbia, *US v AT&T Co.*, 552 F. Supp. 131, August 1982). If this case led to the incumbent break up, the key stone of the remedies consisted in a mandatory and undistorted access to the network guaranteed for all the *baby bells*, e.g., for all the downstream competitors in the telecommunication services markets. In the case at hand, the EFD was implemented in the framework of a market building strategy in the context of the sector liberalization. Such a strategy is also at stake through the EU directives promoting a structural unbundling of vertically integrated State owned monopolies in field of utilities. However, the EFD was not crafted in the field of network industries deregulation but as a competition tool 70 years before.

Indeed, the first occurrence of this concept can be found in the US Supreme Court case law in *Terminal Railroad Association* (224 U.S. 383, 1912). The Supreme Court admitted that while the unification of railroad facilities in Saint Louis, Mississippi, was permissible, considering the efficiency gains it produces, it remains that a refusal to grant access to a competitor to these ones may be analyzed as an antitrust law infringement as it discriminatorily impairs its capacities to access to the market.

Thereupon the agreement among competitors can be analyzed as a combination in the purpose to restraint interstate trade. Throughout the twentieth century several US courts decisions implemented this concept to unilateral and coordinated practices. According to this case law, an access to a bottleneck may be compelled as soon as a competitor has no alternative to enter the market. It was for instance the case in *Associated Press* (326 U.S. 1, 1945), *Lorain Journal* (42 U.S. 143, 1951), *Otter Tail* (410 U.S. 366, 1973), *Hecht Football* (570 F.2d 982, D.C. Cir., 1977), or in *Aspen Skiing* (427 U.S. 585, 1985).

However, the concept of essential facility, and more precisely its implementation within the scope of Antitrust laws, was formally rejected in harsh terms by the US Supreme Court in 2004 in its *Trinko* ruling. Quite surprisingly, according to the Supreme Court, the essential facilities doctrine was never endorsed by its own case law. Insofar as it is not an antitrust concept, it may be used, at best, in the field of sector specific regulation. . . If the US Supreme Court overturned its own long-standing jurisprudence (from 1912 to 1985), it may be related both to the specific conditions of this case (a class-action brought by a law-firm searching for damages) and to the evolution of the academic literature regarding this issue since the 1960s. Indeed, legal scholars have increasingly seen in the implementation of EFD a violation of fundamental rights as property rights or freedom to contract (Areeda 1990).

Such a mistrust is not so surprising considering other courts decisions both from the *Lochner* era (the conservative US Supreme Court case law before the progressive turn of the late 1930s' and the post war *Warren* era) and from the *Chicagoan* turn of the late 1970s. The Supreme Court stated in *Colgate* (250 U.S. 300, 1919) that a company has the power to choose with whom to contract and to set its conditions. Since the market power does not result from a *monopolization* strategy, antitrust laws have not to impose to contract with any other undertaking. In 1980, the *Berkey Photo v. Eastman Kodak* decision (444 U.S. 1093, 1980), confirms that a monopoly, since its

position results from its own merits, can charge the price it decides.

These two judgments have to be placed into their respective proper contexts. The first one is representative of the *classical legal thought*. Neither antitrust laws nor public regulations have to impair fundamental rights. The second one is typical from the *Chicagoan* approach of antitrust laws enforcement. The *GTE Sylvania* decision (*Continental Television v. GTE Sylvania*, 433 U.S. 36, 1977) widened the scope of the rule of reason at the detriment to *per se* prohibitions. The *Reiter Sonotone* decision (*Reiter v. Sonotone Corp.*, 442 U.S. 330, 1979) endorsed the consumer welfare approach. The *Eastman Kodak* decision confirmed the *Chicagoan* view according to which a monopoly can lawfully extract the competitive rents it had created. In this framework, Antitrust laws only have to sanction the extension of a market power on other basis than the merits. Extracting the surplus created is considered both as legitimate and as desirable in terms of market dynamic (Carlton and Heyer 2008).

Indeed, the Sherman Act, promulgated in 1890, does not prohibit the mere possession of a monopoly power. A monopoly position is not an antitrust issue in and of itself while its acquisition and its maintenance stem from the undertaking's own merits. As the Supreme Court stated in *Grinnell Corp* (384 US 563, 1966) "The offense of monopoly under § 2 of the Sherman Act has two elements: (1) the possession of monopoly power in the relevant market and (2) the willful acquisition or maintenance of that power as distinguished from growth or development as a consequence of a superior product, business acumen, or historic accident." As a consequence, the notion of merits goes far beyond the scope of considerations narrowly related to past investments or to the risks initially taken by the incumbent.

Such a view contrasts with the underlying logic of the Judge Learned Hand's ruling in *Alcoa* (148 F.2d 416, 2d Cir. 1945). According to the current dominant conception of antitrust laws enforcement, a monopolist is not bound to adjust its market behavior in order to guarantee a *living*

profit to its competitors. On the contrary, Learned Hand considered that a vertically integrated undertaking that enjoys a monopoly position on the upstream market must set its prices in a manner that allows its downstream competitors to remain on the market, whatever their efficiency. This position is at odds with US current case law according to which a *legitimate* monopolist has no duty towards its downstream competitors. However, the situation may be different in regulated industries for which the market positions are not only related to the merits. This is precisely the point stressed by the Supreme Court in *Trinko*: the EFD is no longer seen as an antitrust-related concept but only as remedy available to a sector specific regulator to organize the third party access to a *natural monopoly* network.

A Risk in Terms of Incentives According to the Economic Literature

Economic scholars have also harshly criticized the implementation of the EFD in the competition law field. Its broad implementation may lead to bind a successful firm to make its competitors benefit from its past investments, e.g., to free-ride them. Such a mandatory access may pertain to an asymmetric regulation of competition and it may have a deterring effect on its incentives to invest. *Ex post*, imposing an access to the incumbent's assets can be seen as an expropriation. The undertaking controlling the essential facility is deprived of the right to refuse the access and of its capacity to set freely its price. The economic gains resulting from its investment will be partially lost. *Ex ante*, anticipating such a risk might deter to invest in this type of asset. Depending on the level of the access charge, it may also impair its incentives to spend money in its maintenance or in its development, as the dominant undertaking cannot expect to extract all the economic gains resulting from its investment. In addition, it may even impair the incentives to invest for nondominant undertakings. As the new entrants may prefer to use the incumbent's assets, it may reduce the incentives to develop a new (essential) facility. Indeed, this case law may lead to expect the possibility to be bound to provide an access benefiting to competitors and in doing so to reduce the

potential pay-offs associated to the initial investment.

As a consequence, imposing a mandatory access may be welfare-enhancing only in a static sense: it effectively increases the competition on the downstream market. However, in a dynamic sense, it may be a counterproductive remedy as it hinders the incentives to invest in the infrastructure and in strategies aiming at by-passing it. The consumer welfare gain resulting from the competitive remedy may be only a short-term one. Investments aiming at producing disruptive innovations may be discouraged and the asset owner may be daunted to invest to increase the quality of the service provided by its infrastructure or its capacities because it will also benefit to its competitors. In a worst-case scenario, the incumbent might be incentivized to under-invest to generate socially counter-productive bottlenecks in order to have an objective reason to deny the access to its competitors.

In addition, the very cautious approach of the economic literature considering the EFD implementation is even exacerbated for intangible assets as intellectual property rights (hereafter IP). For instance, how to characterize an intangible asset as absolutely necessary to a competitor to access the market and reasonably impossible to replicate in technical or in financial terms? Such preventions echo with the Stigler (1968) views according to which barriers to entry cannot really be technical or financial but are more commonly the product of public regulations. Moreover, public intervention through antitrust remedies are viewed with suspicion. It is particularly the case since these remedies are implemented within market building objectives (or in order to counterbalance individual market power) or since they aim at correcting the excess of IP rights protection. The risk of regulatory capture cannot be excluded.

Indeed, we may put into relief the long-standing mistrust of economic scholars towards antitrust suits initiated by competitors. The risk is to protect unduly competitors at the expense of consumers (Bork 1978). In addition, the incentives produced by competitive threats might be still possible despite a monopoly situation. The competitive pressure persists for as long as the

market remains a constable one. Compelling a monopoly to renounce to its contractual freedom and to limit its capacity to extract all the surplus created can eventually be prejudicial in terms of consumer welfare. In other words, compulsory licensing or mandatory access may lead to an asymmetric regulation of competition. If the EFD one may be acceptable as a regulatory tool in the framework of a sector specific liberalization, it is by far more debatable since the dominant undertaking's position is due to its merits and not to former exclusive rights.

A Broad Acclimatization in the EU Competition Law Enforcement

Even through the essential facility doctrine is now rejected as an antitrust tool in the USA, its implementation by the EU Commission and by the Member States' competition authorities is significant. The reason of this adherence may be explained by the EFD theoretical consistency with some of the EU competition policy underlying principles. Firstly, the EFD tackles the issues related to deny to access to the market (exclusionary abuse) or to excessive access prices (exploitative abuses). Secondly, as soon as the purpose of the competition law is conceived as encompassing the building competitive markets or the guarantee a level playing field, the EFD appears as an efficient tool to craft remedies to achieve such ends.

Implementation to Network Industries

The first uses of the EFD in the EU context naturally took place in the field of the liberalization of network industries with the 1992 EU Commission's decision in the case *B&I – Sealink* (Commission, case IV/34.174 – Sealink/B&I – Holyhead, 11 June 1992). It was also the case, 4 years later in the French case the 1996 competition authority's decision related to the Narbonne's heliport (French Competition Council, decision n°96-D-51, 3 September 1996). Through the EU Commission led liberalization process, the EFD was successively applied to telecommunications, electricity, gas, and railways sectors. We will see below that one additional special feature of the EU use of the EFD compared

to the US case has to be taken into account: its large implementation to intangible assets. For instance, incumbents are commonly bound to share their consumer's data bases with new entrants in order ensure a level playing field (see for instance the French Competition Authority decision, n°17-D-06 related to practices in the markets of gas natural, electricity, and energy related services, 21 March 2017).

The EFD was often implemented as a competitive remedy in the sectors concerned by a liberalization process. The first step of liberalization commonly consists in guaranteeing an open (and regulated) access to the incumbent's infrastructure for the new entrants in order to favour the development of a services-based competition. The second step may be an unbundling (incumbent's vertical de-integration) or the implementation of the so-called *ladder of investment approach* (Bourreau et al. 2010).

The vertical unbundling is a drastic way to guarantee an undistorted access. It consists in the vertical integrated incumbent break up, as it was the case in the 1982 *AT&T* US case. These remedies were implemented in the energy sector exclusively through negotiated procedures (see for instance the *ENI* Commission decision 39.315, 29 September 2010).

The ladder of investment approach is a less intrusive intervention (without mandatory divestitures as structural remedies) that can be implemented since the competition is not potentially limited to the service but can be expanded to a part of the facilities. This approach consists in providing a broad access to the incumbent's facilities in the first steps of the liberalization process in order to lower barriers to entry at the benefits of its new competitors. The expected effect consists in helping them to acquire a sufficient customer's portfolio to overcome investors' risk aversion to finance their own infrastructures. This broad access will be progressively reduced in order to promote incentives to invest both for them and also for the incumbent, since the first ones cannot durably free ride its own investments. This approach allows to incentivize the new entrants to shift from a services-based competition to a facilities-based one. It does not concern the

natural monopoly in itself but all the facilities necessary to the connection with this one. Naturally regulated access to the natural monopoly segment remains at the end of this period. One of the interests of such a facilities-based competition is to favour a service differentiation among the competitors, for instance in terms of quality. It can be seen as broad way to implement the EFD within the context of a sector specific liberalization.

Even so, the case of the ladder of investment approach illustrates some of the common risks and pitfalls of the EFD implementation in network industries. On one hand, if the access charge is too low, the new entrants may free ride incumbent past investments and can be discouraged to invest in their own assets. On the other hand, the incumbent's incentives to develop and to maintain its own infrastructures may be reduced by such a mandatory access. Setting the access charge raises several difficulties. A high access charge level may erect a barrier to entry and unduly preserve incumbent's rents. Even if the access charge has to be oriented to its costs, it remains that information asymmetries might lead to significant regulatory costs and to possible suboptimal settings. In the same time, the access to the incumbent's facilities may be counterproductive for the new entrants as it might perpetuate a situation of dependence toward their main competitor. This dependence on the facilities controlled by their main competitor exposes them to the consequences of noncooperative behaviors as raising rival costs strategies (through the pricing of nonregulated ancillary services) or strategies aiming at artificially reducing the quality of the service they provide to final users.

The EU Commissions have faced sharp criticisms about its broad implementation of the EFD in the field of network industries. The concept of ladder of investments, presented above, illustrates that the scope of the essential facility can go far beyond the natural monopoly segment narrowly defined. The risk is to excessively extend the notion of essential facilities to all the specific and expensive assets that a new entrant needs to dispose to enter the market. Investing in some specific assets may actually represent a significant risk as their amortization can be difficult for a new

entrant who only serves a small segment of the market. However, it is not so rather clear at the theoretical point of view that such investments can be considered as barriers to entry (see for instance Stigler 1968). The risk is to promote thought the EFD implementation an asymmetric regulation of the competition by mandating the incumbent to provide an access not only to its essential facilities but also to *convenient facilities* for its competitors (Ridyard 2004). The risk is to favor inefficient entries at the expense on final consumers.

A striking example of such concerns can be provided by the EU Commission *GVG* decision in 2003 related to an access of a German company to the Italian railways. The mandatory access covers all the components of the traction services encompassing the locomotives and the railway workers qualified for the Italian network themselves (European Commission, case COMP/37.685, *GVG/FS*, 27 August 2003). On the contrary, in the *Bronner* decision, the Court of Justice had decided that a mandatory access to an incumbent facility cannot be imposed since the new entrant can develop its own (Court of Justice, judgment C-7/97, *Oscar Bronner GmbH & Co. KG v Mediaprint Zeitungs, 26 November 1996*). An essential facility should be a non-replicable one and not only a less expensive one. The EU case law has been overturned at the benefit of a broader definition of the notion of the essential facility.

Another spectacular example of the broad implementation of the EFD in the EU competition policy applied to the liberalisation of network industries can be provided by a French competition authority decision related to the electricity market in December 2007, *Direct Energy* (French Competition Council, decision n°07-D-43 related to EDF market practices, 10 December 2007). These far reaching remedies can be explained by the very specific context of the French liberalization characterized by the coexistence of regulated tariffs at the retail level and market prices at the wholesale one. The new entrants were bound to set their retail prices at this threshold to attract customers. In the same time, as they did not control their own generation

capacities, they must buy the electricity on the wholesale market. Since, the regulated retail price is set according to the generation marginal cost of the plants, mainly nuclear, operated by the incumbent, they were potentially squeezed since the wholesale price might be higher than this last one. The competitive claim was grounded on this margin squeeze produced by the combined effect of the downstream (regulated) price and the upstream (market) price. The competition law-based remedy consisted in implementing the EFD to the energy generated by the nuclear power plants (de Hauteclocque et al. 2011). The new entrants benefit from a drawing right on the incumbent's nuclear plants originated generation. The EFD was implemented to energy itself through this quasi-structural remedy. Such types of remedies tend to ensure that the new entrants may be as efficient as the incumbent. The use of the EFD is not limited to guaranteeing an access to the market for the competitors of a vertically integrated incumbent but participates to a regulation of the competition. In other words, the access does not concern a network infrastructure but the upstream good. The purpose is to ensure a level playing field in the downstream market. . . even if it supposes to "subsidize" potentially less efficient competitors. The EFD in this context leads to horizontal wealth transfer among market players. In this instance, it was used to address a regulatory imperfection.

Implementation to Intellectual Property Rights

Beyond this broad implementation, the EU implementation of the EFD is also distinguishable from the US one, as it also broadly concerns intangible assets as intellectual property rights. The EFD was implemented in the EU case law on TV programs, data bases, and to interoperability devices between softwares. While the EFD as competition remedies may be admitted as the essential facility at stake resulted from exclusive rights, the case of intangible assets raises concerns as soon as the assets are the products of incumbent's merits. In the same time, these far reaching remedies can be analyzed as a mean to counterbalance the excessive protection of the incumbents produced by intellectual property rights. They can also be

analyzed as a mean to prevent an unchallengeable monopolization of a given market or to counteract leveraging strategies. The leverage from the then near-monopoly Windows operating system was one of the main concerns 11 years ago (EU Court of First Instance, case T-201/04, *Microsoft Corp. v. European Commission*, 17 September 2007); (EU Commission, 18 July 2018, case 40099) and some online platforms raise nowadays the same types of competition issues.

In a historical perspective, the first implementation to the EFD to intangible assets in the case of the EU competition law took place in the 1990s with the Irish TV programs case (EU Court of Justice, cases C-241/91P and C-242/91P, *RTE v European Commission*, 6 April 1995). The dominant broadcasting operator edited its own TV programs magazine and refused to provide its TV listings to a new entrant who aimed at proposing a multi-channels TV programs magazine. The 1995 EU Court of Justice rulings imposed to communicate to this entrant the TV listings by considering that the refusal impair it to propose a new product to consumers. A second emblematic case was the IMS Health one (EU Court of Justice, case C-418/01, *IMS Health GmbH v NDC GmbH*, 29 April 2004). An undertaking proposing software-based reporting tools for pharmaceutical sales data refused that a new entrant adopts the same database modular structure than its one, based on German Zip codes. The EU Court of Justice dismissed its claims in 2004 and considered that it must provide a licence for allowing its competitor to use the same database structure despite its protection through intellectual property rights. What is specific in this second case is that there is no new product at stake as it was the case in the 1996 ruling.

This point is all the more relevant that the initial EU case law imposed to fulfil several criteria to decide of a compulsory licensing remedy under the EFD. The 1995 Magill decision was for instance grounded on the future availability of a new product for consumers. In the IMS judgment, this condition was not required. The access may be required even if the new competitor will provide the same service in the same relevant

market. In the same way, in the Microsoft case, the Commission imposed as a remedy the sharing of the interface protocols with its OS, considering that the interoperability will favor the future development of new products. Such pragmatism was also at stake concerning another condition to implement the EFD for intangible assets as for instance the requirement to implement a balance of incentives before imposing a licensing. Indeed, the EU case law initially imposed to perform such a balance in order to assess the net effect on the incentives to invest and to innovate both for the incumbent and for the beneficiary of the compulsory licensing. Such an assessment, which echoes with the more economic approach of the competition law enforcement – e.g., its effects-based approach – is seldom, or almost never, implemented in the EU case law related to the EFD (Marty and Pillot 2012). In the EU Commission guidance related to its enforcement priority regarding the article 82 of the Treaty (now the article 102), issued in February 2009, only three criteria remain: the refusal must relate to a product or a service objectively necessary to effectively compete on the market; the refusal may lead to an elimination of the effective competition; and this refusal is likely to lead to consumer harm).

Discussion

Implementing the EFD for intangible assets raises specific concerns (Castaldo and Nicita 2007). Setting the licensing fee is one of the more delicate aspects. Defining the access charge for a physical network may already be a challengeable task. Even though the principles are clear (the access price should be oriented toward the cost), the influence of accounting choices and the imperfections of information may lead to significant difficulties. Moreover, if we consider the Direct Energy remedies how to set the real cost of an electricity generated by nuclear power plants? The solution applied in this specific case – an auction procedure – illustrates the difficulties encountered to implement such remedies. Things are even worse for intangible assets for which the cost are by far more difficult to assess. The access

and replication costs are negligible. The initial investments and the risks taken cannot be easy to evaluate and may be irrelevant, as testifies the IMS case, in which the essential facility at stake was an IP right on the structure of data base in accordance with Zip codes.

In addition, a broad implementation of the EFD to intangibles might lead to price regulation and to some extend to competition regulation. Defining the terms of a FRAND licence terms (*Fair, Reasonable, and Non Discriminatory*) or balancing market powers among competitors impose to define the concepts of fairness and reasonableness. Furthermore, using the EFD to promote the liberalization of a network industry, or even worse to make a dominated market contestable, may lead the competition authority to act as a sector specific regulator aiming at favoring the development of the competitors, possibly at the expense of final consumers.

Finally, the EFD implementation as a competition law remedy illustrates the transatlantic divergences on several topics. First, it stresses the debates on the respective scopes of competition law enforcement and sector specific regulation. Second, it illustrates the divergences about the possibility to use competition remedies to address issues as the excessive protection granted by intellectual property laws. Third, it underlines the disagreements on the use of competition law remedies as tools to prevent or to correct excessive concentrations of economic powers, even if these ones mainly result from the merits.

However, a striking point in the analysis of the implementation of the EFD in the EU competition law enforcement should be put into relief. It consists in the sharp contrast between the frequency of its use and the reluctance of the competition authorities to ground decisions and to justify remedies explicitly on this doctrine. Several reasons might be highlighted. A first one may be found in its lack of well-grounded economic theory foundations, especially in the framework of an effects-based approach (Geradin 2004). A second one may be related to the relative fuzziness of the concept at legal point of view and to the possible risks induced in terms of decision reversal in the judicial control. As a consequence, the doctrine is

in the same time significantly used to shape competition law remedies in the EU case and rarely qualified as a legal basis to ground them.

EU Microsoft Competition Case

Luca Rubini

University of Birmingham, Birmingham, UK

Abstract

The investigation and litigation that involved Microsoft before the EU authorities in the 2000–2012 period is arguably the first case that put the complex issues of the new economy to the test of EU competition laws. The case, which attracted a lot of attention, also beyond competition law circles, was a complex one, at various levels – technical, economic, and legal – and one that eventually interrogated the ultimate goals of competition policy in a given legal system. This entry takes the reader through the various issues and findings of the European Commission and the Court of First Instance of the European Union before offering few notes of analysis and a view on the future implications of this landmark case.

EL classification K4 Legal Procedure, the Legal System, and Illegal Behavior.

Background and Significance of the Case

“The Microsoft case was the monopolization case of the new economy just as *Standard Oil* had been the icon of the old” (Peritz 2010). This quote makes reference to the US case involving Microsoft and draws a momentous parallel with the famous *Standard Oil* case of 1911 where the US Supreme Court found Standard Oil guilty of monopolization of the petroleum industry and famously divided the company into several different and competing companies. This quote gives a very good idea of the importance of the competition law tangles that have involved Microsoft, the American new economy giant, in the USA. Equally important was the investigation and litigation that involved Microsoft in the EU in the 2000s and which produced some of the most

controversial decisions of the EU Commission and of the General Court.

Microsoft, founded by Bill Gates in the 1970s in California, has fast become one of the most successful companies of our time. It belongs to that inner circle of businesses strongly characterized by a unique blend of innovation and creativity and vision and aggressiveness – which can often be attributed to the leadership of unique founder individuals. Microsoft operates in some of the most crucial and innovative markets. Its products, and notably its operating systems and software applications, are ubiquitous. Their importance cannot be understated. They have influenced, indeed shaped, everyday life of billions of people around the world. Commercial success and especially market power attract the attention of antitrust control. Microsoft has thus been subject to various investigations and actions, based on antitrust laws, at both sides of the Atlantic. Since the beginning of the 1990s, Microsoft started to be the subject of the scrutiny of US authorities (on the US case, see Page and Lopatka 2007; Peritz 2010; Gavil and First 2014). This culminated in a much-publicized litigation at the turn of the millennium where it was charged with the allegedly illegal tying of the Internet Explorer web browser with the Windows operating system. Microsoft would have leveraged on the sheer dissemination of its PC operating system to extend its dominance in the web browser market. Following, among other things, a change in administration (from Clinton to Bush Jr.) and numerous settlements between the various parties involved, this litigation finished with no action. The focus shifted to the other side of the Atlantic. At the beginning of the 2000, the EU Commission officially started to investigate two conducts of Microsoft – the tying of its media player with Windows and the refusal of certain interoperability information to communicate with its server operating systems – which, in a momentous decision of 2004, were concluded to be breaches of EU antitrust law. In 2007, in a long-awaited decision, the General Court of the EU essentially confirmed the findings and rulings of the EU Commission. In 2009, the EU Commission started a new investigation focused (like the US

case) on the bundling of Windows with Internet Explorer, which was settled the next year.

After summarizing the arguments and the findings of the EU case (section “[The Decisions of the EU Commission and the General Court](#)”), this entry provides few notes of analysis of the technical, economic, and legal aspects of this case (section “[Analysis of the Case](#)”). This analysis paves the way to the consideration of the broader implications of the case (section “[Implications for the Future](#)”).

The Decisions of the EU Commission and the General Court

Article 102 of the Treaty on the Functioning of the EU (TFEU) (formerly, Article 82 of the EC Treaty) was the key provision at the center of both the EU Commission investigation and the litigation before the General Court. In the parts relevant to the Microsoft case, this provision, which dates back to the original Treaty of Rome of 1957, reads:

Any abuse by one or more undertakings of a dominant position within the internal market or in a substantial part of it shall be prohibited as incompatible with the internal market in so far as it may affect trade between Member States.

Such abuse may, in particular, consist in:

...

(b) limiting production, markets or technical development to the prejudice of consumers;

...

(d) making the conclusion of contracts subject to acceptance by the other parties of supplementary obligations which, by their nature or according to commercial usage, have no connection with the subject of such contracts.

The reader can find in the literature (Rubini 2010) a uniquely interesting repetition of the EU investigation and litigation, performed by its very same actors: the Commission (Banasevic and Hellström 2010), Microsoft (Forrester 2010; Bellis and Kasten 2010), and the General Court (Vesterdorf 2010). The following section summarizes the key arguments and findings of the case. This overview will introduce the reader to the various levels of complexity of this momentous case.

The Decision of the EU Commission

After a lengthy investigation, the EU Commission issued its decision on 24 March 2004. It concluded that Microsoft had violated Article 82 of the EC Treaty by abusing its dominant position in client PC operating system (OS) in two ways. Firstly, it had illegally refused to supply interoperability information which was indispensable for rival vendors to compete in the work group server operating system market. Secondly, it had illegally made the availability of the Windows client PC operating system conditional on the simultaneous acquisition of the Windows Media Player software. The Commission ordered Microsoft to disclose interoperability information and appointed a trustee to monitor the compliance with this duty. It also ordered Microsoft to provide a version of Windows without Windows Media Player. The Commission finally imposed a fine of 497,196 million euros for what it found to be a very serious infringement of Article 102 TFEU.

With respect to the **licensing** part of the case, the Commission found that Microsoft had breached Article 102 TFEU by refusing to supply interoperability information to its competitors. As noted, letter (b) of the same provision enlists: “limiting production, markets or technical development to the prejudice of consumers.” Two Microsoft products, and markets, were under examination in the licensing claim: first, the Windows PC OS and, second, the Windows Server OS. The Commission found that, with market shares of, respectively, 93% and 60%, Microsoft was superdominant and dominant in the relevant product markets. The servers’ market was the one where there had been, and there still was, some competition. Some companies were competing with Microsoft and were concerned by the reduction in the interoperability information available for communication between their servers and Windows PCs. The main issue of contention concerned the degree of interoperability, and amount of information, which should be guaranteed. The Commission opined that Microsoft refused information that was indispensable for external servers to interoperate with Windows, which limited innovation and risked eliminating competition to the detriment of consumers. In

economic terms, the scenario was one of leveraging in the server OS market on the basis of the virtual monopoly held in the PC OS market. The significant network effects that are typical of these markets exacerbated the effects of this exclusionary conduct (Gil-Moltó 2010). The Commission therefore ordered Microsoft to license on reasonable and nondiscriminatory terms the relevant interoperability information to its competitors.

With respect to the **tying** claim, the Commission found that Microsoft had infringed Article 102 TFEU by bundling its Windows Media Player with its operating system. This had enabled Microsoft to expand its market power and foreclose competition in the media player market. The Commission based its decision on four steps: (i) the tying (i.e., Windows) and tied (i.e., Windows Media Player) products are separate products, (ii) Microsoft is dominant in the market for Windows, (iii) it does not give its customers a choice to obtain the tying product without the tied product, and (iv) this practice forecloses competition (in market of media players). The Commission thus ordered Microsoft to offer a version of Windows without the Windows Media Player.

The Judgment of the EU General Court

With a decision dated 17 September 2007, the General Court (at the time Court of First Instance) of the EU upheld the substance of the Commission’s decision with respect to both abuses as well as the fine. The General Court’s decision was not appealed before the Court of Justice of the EU.

The Duty to Disclose Interoperability Information
Before the General Court, Microsoft put forward various arguments to discredit the assessment of the EU Commission of the need for a duty to disclose interoperability information. Firstly, the concept of interoperability used by the Commission was too broad, and to follow it would have meant to enable Microsoft’s competitors to have access to highly technologically innovative protocols and to clone its products. Secondly, the Commission did not follow the strict conditions that, according to the case law, need to be present before antitrust law can impose a duty to license

intellectual property. In particular, the presence of five alternative routes for interoperability defeated the existence of indispensability. In addition, a high threshold for antitrust intervention should be followed. The presence of competing servers in the market proved that competition was not being eliminated. Moreover, the emergence of no “new product” was prevented by Microsoft’s conduct. Finally, Microsoft’s refusal was justified on the grounds of protecting valuable intellectual property, and the forced disclosure of information would encourage copying and reduce incentives to innovate.

The General Court in turn rejected each of these arguments.

Firstly, the General Court confirmed the degree of interoperability the Commission found to be necessary to remain viable in the market and in the specific context of a Windows work group network (paras. 229–230). In particular, the Court found that the Commission was right in concluding that “the common ability to be part of [the Windows domain architecture] is a feature of compatibility between Windows client PCs and Windows work group servers” (para. 189). Consequently, the Commission was held to be correct in considering that the required interoperability information should cover “the complete and accurate specifications for all the protocols [that are] implemented in Windows work group server operating systems and that are used by Windows work group servers to deliver file and print services and group and user administration services, including the Windows domain controller services, Active Directory services and Group Policy services, to Windows work group networks” (para. 195). The Court also noted that this information does not extend “to the internal structure or to the source code of its products” (para. 206). The Court also rejected Microsoft’s argument that this degree of interoperability would have allowed its competitors to clone its products or certain features of those products (paras. 234–242).

Secondly, the General Court also found the Commission did not err when it found that the information concerning the interoperability with the Windows domain architecture was **indispensable**. The availability of the required information was

necessary in order to be able to compete viably with Windows work group server OSs on an equal footing.

On the one hand, the Court rejected that the five alternatives to disclosure could ensure the necessary degree of interoperability. Microsoft had put forward five methods which, though not ensuring the perfect substitutability that the Commission considers essential, made nonetheless it possible to achieve the “minimum level of interoperability required for effective competition,” “to work well together” (paras. 345–346). It is interesting to note here that, in its Decision, the Commission had already rejected “reverse engineering” as a viable alternative to disclosure of interoperability information (see para 562 of the Decision).

On the other hand, on the issue of what level of **elimination of competition** is necessary to trigger antitrust intervention, Microsoft contended that the Commission had been satisfied with establishing a mere “risk” of the elimination of competition in the work group server OS market. What should have been required was the “likelihood” or, in other words, the “high probability” of distorting competition. The General Court responded that Microsoft’s complaint was “purely one of terminology” and “wholly irrelevant” (para. 561). The Court went on noting,

The expressions ‘risk of elimination of competition’ and ‘likely to eliminate competition’ are used without distinction by the Community judicature to reflect the same idea, namely that Article [102 TFEU] does not apply only from the time when there is no more, or practically no more, competition on the market. If the Commission were required to wait until competitors were eliminated from the market, or until their elimination was sufficiently imminent, before being able to take action under Article [102 TFEU], that would clearly run counter to the objective of that provision, which is to maintain undistorted competition in the common market and, in particular, to safeguard the competition that still exists on the relevant market.

In this case, the Commission had all the more reason to apply Article [102 TFEU] before the elimination of competition on the work group server operating systems market had become a reality because that market is characterized by significant network effects and because the elimination of competition would therefore be difficult to reverse. . . .

Nor is it necessary to demonstrate that all competition on the market would be eliminated. What matters, for the purposes of establishing an infringement of Article [102 TFEU], is that the refusal at issue is liable to, or is likely to, eliminate all effective competition on the market. It must be made clear that the fact that the competitors of the dominant undertaking retain a marginal presence in certain niches on the market cannot suffice to substantiate the existence of such competition (paras. 561–563).

Applying this reasoning to the actual market data, the General Court concluded that “Microsoft’s refusal has the consequence that its competitors’ products are confined to marginal positions or even made unprofitable. The fact that there may be marginal competition between operators on the market cannot therefore invalidate the Commission’s argument that all effective competition was at risk of being eliminated on that market” (para. 593).

Citing the previous case law, Microsoft argued that it has not been established that its refusal prevented the appearance of a “new product” for which there is unsatisfied consumer demand. The General Court noted that the appearance of a new product “cannot be the only parameter which determines whether a refusal to license an intellectual property right is capable of causing prejudice to consumers” (para. 647). Such prejudice may arise, as the Commission had found, also when there is a limitation of technical development, as provided in Article 102 TFEU, letter (b) (*ibid.*).

The General Court then endorsed the Commission’s finding that “the information at issue does not extend to implementation details or to other features of Microsoft’s source code,” representing “only a minimum part of the entire set of protocols implemented in Windows work group server operating systems” (paras. 657–658). Nor – the Court noted – “would Microsoft’s competitors have any interest in merely reproducing Windows work group server operating systems.” Once the necessary interoperability information is made available, “they will have no other choice, if they wish to take advantage of a competitive advantage over Microsoft and maintain a profitable presence on the market, than to differentiate

their products from Microsoft’s products” (para. 658).

Finally, the General Court noted that the mere fact that the relevant technology is covered by intellectual property protection is not per se a sufficient objective justification (para. 690). Microsoft had not sufficiently established that, if it were required to disclose the information, disclosure would have a significant negative impact on its incentives to innovate (para. 701).

The Bundling of the Windows Media Player

As regards the tying claim, the analysis immediately focused on whether the Commission introduced new law in the area by examining whether the dominant undertaking “does not give customers a choice to obtain the tying product without the tied product” (para. 845). The General Court dismissed Microsoft claim that this was any different from what Article 102 EC (d) requires, i.e., that bundling assumes that consumers are compelled, directly or indirectly, to accept supplementary obligations, such as those referred to in Article 102(d) EC (para. 864). The Court points out that “coercion is mainly applied first of all to OEMs [Original Equipment Manufacturers], who then pass it on to the end user” (para. 865). The analysis then shifted to the question whether the Commission introduced a new condition, analyzing whether Microsoft’s conduct foreclosed competition. Microsoft accused the Commission of having added a new test, nor provided for in the law (and in particular Article 102 TFEU, letter d), notably that the tying conduct is foreclosing competition (para. 846). The Court acknowledged that, in light of the specific circumstances of the case, the Commission did not “merely assume, as it normally does in cases of abusive tying, that the tying of a specific dominant product has by its nature a foreclosure effect” (para. 868). By contrast, it “examined more closely the actual effects which the bundling had already had on the streaming media player market and also the way in which that market was likely to evolve” (*ibid.*). The Commission was right in doing this, since the “list of abusive practices set out in the second paragraph of Article 82 EC is not exhaustive and that the practices

mentioned there are merely examples of abuse of a dominant position” (para. 860). More specifically, bundling by an undertaking in a dominant position may also infringe Article 82 EC where it does not correspond to the example given in Article 82(d) EC. Accordingly, in order to establish the existence of abusive bundling, the Commission was correct to rely in the contested decision on Article 82 EC in its entirety and not exclusively on Article 82(d) EC (para. 861). The Court, in any event, concluded that constituent elements of abusive tying identified by the Commission coincide effectively with the conditions laid down in Article 82(d) EC (para. 862).

The second point of contention focused on whether media functionality is a separate product from the PC operating system, which is a necessary condition to have tying. Microsoft argued this was not the case (para. 912). Media functionality forms an integral part of the operating system with the consequence that what is at issue is a single product. This would have been confirmed by customers’ expectation that any PC OS have essential audio and video functionalities. While recognizing the rapid evolution of the industry, where products that are initially separate are then subsequently regarded as forming a single product, the Court concluded that the Commission was correct to find two separate products in the period of the investigation (paras. 913–914). The Court noted that there exists a separate consumer demand for streaming media players (para. 917). The simple fact that two separate products are complementary does not exclude their difference (paras. 921–922). The Court confirmed the Commission’s finding that media functionality is not linked, by nature or by commercial usage, to PC OSs (para. 938). Firstly, it does not seem that the two constitute by nature indissociable products (para. 939). In any event, the Court importantly underlines that “it is settled case-law that even when the tying of two products is consistent with commercial usage or when there is a natural link between the two products in question, it may none the less constitute abuse within the meaning of Article 82 EC, unless it is objectively justified” (para. 942). Secondly, “it is difficult to speak of commercial usage in an industry that is 95%

controlled by Microsoft” (para. 940). Furthermore, the fact that vendors of competing client PC OSs also bundle those systems with a media player was not conclusive (para. 941). The Court crucially noted that “it is settled case-law that even when the tying of two products is consistent with commercial usage or when there is a natural link between the two products in question, it may none the less constitute abuse within the meaning of Article [102 TFEU], unless it is objectively justified” (para. 942). Microsoft’s argument that the integration of Windows Media Player in the OS was dictated by technical reasons was found not to be substantiated (para. 937).

There was no real contention with respect to Microsoft’s dominance in the PC OS market (para. 870) or with respect to the inability of consumers to obtain Windows without Windows Media Player (para. 961).

The Court then moved to the actual assessment of how Microsoft’s conduct would have foreclosed competition; the General Court upheld the Commission’s analysis.

Microsoft contended that the Commission, recognizing that it was not dealing with a classical tying case, had to apply a new and highly speculative theory, relying on a prospective analysis of the possible reactions of third parties, in order to reach the conclusion that the tying at issue was likely to foreclose competition. The General Court noted that “it is clear that, owing to the bundling, Windows Media Player enjoyed an unparalleled presence on clients PCs throughout the world, because it automatically achieved a level of market penetration corresponding to that of the Windows client PC operating system” (para. 1038). The pre-installation of Windows Media Player made users less likely to use alternative players (para. 1041). The said bundling created disincentives for OEMs to ship third-party media players on their client PCs for technical (e.g., higher usage of hard-disk space, risk of confusion on the part of users, increase of customer support and testing costs) and economic (e.g., higher price of the PC) reasons (paras. 1043–1045). The Court also found that the Commission was also correct to find that methods of distributing media players other than

pre-installation by OEMs could not offset Windows Media Player's ubiquity (paras. 1049–1057). The Court confirmed the Commission's finding that the market for streaming media player was characterized by significant indirect network effects (paras. 1061–1076). That expression describes the phenomenon where the greater the number of users of a given software platform, the more there will be invested in developing products compatible with that platform, which, in turn, reinforces the popularity of that platform with users (para. 1061).

Finally, Microsoft's arguments that the integration of media functionality in Windows was "indispensable in order for software developers and internet site creators to be able to continue to benefit from the significant advantages offered by the "stable and well-defined" Windows platform" were rejected (para. 1146). The Court further noted that, although standardization may be positive (but not necessarily wanted by third parties), it cannot be allowed to be imposed unilaterally by a dominant firm (paras. 1152–1153). Similarly, the claim that the Commission was interfering with Microsoft's business model was not accepted (paras. 1149–1150). The Commission did not deny that Microsoft could provide a version of Windows with Windows Media Player. It objected to the fact that this is the only available version and, more specifically, that no version of the ubiquitous OS is offered without Windows Media Player.

Analysis of the Case

The summary exposition of section II gives a good flavor of the complexity of this case. Indeed, it is various factors of technical, economic, and legal nature, each adding to the other, that make it complex. In turn, this complexity explains how the assessment of both the EU Commission and the General Court could be so controversial and generate much debate. Quite probably, the most interesting remarks in this discussion come from Bo Vesterdorf, the President of the General Court in the very same case, who, focusing on the duty to disclose interoperability information, expressed

concerns about the possible negative impact of the General Court's decision on investment and innovation (Vesterdorf 2008).

The first layer of complexity comes from the highly **technical** nature of the subject matter. What clearly comes out from an overview of the literature is that, without a proper understanding of the "basic technology" issues, any economic or legal assessment is doomed to fail (see the excellent primer of Jackson 2010). The "technical basis" of the EC case "was significantly more complex than its US counterpart," but, unfortunately, "many of the articles written about the Microsoft proceedings fail to convey the technical complexity of the issues at stake" (Jackson 2010). It is sometimes (wrongly) assumed that the computing sector is just like any other industry and that a stylized account of the technical facts would suffice. It should also be highlighted that it is in particular the "interoperability" part of the case that requires an unusually detailed level of technical understanding, which probably explains why this claim attracted particular attention. To name just few of the technical issues of the case and indeed the most general ones: What is interoperability? In particular, what degree of interoperability is necessary for computer programs to be meaningfully interfaced? Consequently, what type of information is necessary? Apart from disclosure, what paths are available to software developers to obtain this information? What difficulties do they each involve? How effective are they to ensure interoperability? What does define a set of instructions as a computer program? Is it possible to distinguish the latter from a mere functionality? When do separate computer programs stop being so and become one single program? Can functionalities be removed from a computer program without impairing the integrity of the program? (for a discussion of these questions, see Walsh 2010; Andreangeli 2010).

The second level of complexity, which is directly based on the first one, concerns the **economics** of this sector and of the behavior of consumers and competitors. Some unique features characterize the computer industry, such as its very fast pace of development and innovation and the high relevance of network effects (see

Gil-Moltó 2010; Walsh 2010; Liebowitz and Margolis 2001; Evans et al. 2000). Thus, on the one hand, the tendency toward network effects makes foreclosure more likely. On the other hand, the fast development of the industry where today's winner is tomorrow's loser (and vice versa) represents a crucial concern for legal and regulatory processes, in two respects. First, the speed and uncertainty of change may make the assessment of harm and efficiencies difficult. Second, the time required for investigations may render legal processes continually and, inherently, obsolete. Equally, in such a dynamic environment, remedies are difficult to be tailored and effective (Economides and Lianos 2010).

The third, and final, level of complexity lies in the law. After almost 60 years from its entry into force, the provision at issue, Article 102 TFEU, is still vague. "Despite a significant volume of case law expanding, refining, clarifying and apparently applying the law, there is still considerable uncertainty about the exact conditions amounting to abuse" (Walsh 2010). The fact is that Article 102 TFEU, with its broad and general language, is a "standard" (rather than a "rule"), which means that the regulator or judge has to define its content on a case-by-case basis (see Kaplow 1992). This process may lead to more accurate results but is certainly more costly and uncertain. This uncertainty is particularly acute in technological sectors like those of the new economy and does significantly depend on the ambiguous signals that come from the first two layers of complexity set out above.

More deeply, the root of the uncertainty of Article 102 TFEU depends on the fact that its meaning changes depending on the different conceptions of what competition and antitrust law should be about, conceptions that succeed and prevail one after the other. In 60 years (and quite probably in many years to come), the language is (and will be) the same, but the understanding of competition policy and of the regulation of unilateral behavior by dominant firms has changed (and will change). What is competition law about? Is it (only) about efficiency? What do we mean by efficiency? Is competition law more about safeguarding a competitive process, characterized

by market access and contestability, or, more simply, an efficient outcome of the market contest? What other competition policy objectives play within the frame of competition law? (For commentary around these questions, see Kerber 2008 and Fox 2008.)

That being said, one has to ask whether the Commission and the General Court have really been revolutionary in their legal analysis. We focus here on the interoperability issue. In particular, did they really depart so dramatically from the previous *Magill* and *IMS Health* case law and their formulation of the "exceptional circumstances" under which a duty to deal and supply can be enforced? Fox (2010) rightly observes that "[t]he Microsoft facts did not fit the factors very snugly; but they fit the concept of essentiality much better than the facts of either *IMS Health* or *Magill*". While the General Court (and the Commission) may have been essentially right, Fox goes on noting that it would have been "much more satisfying" if the General Court had more openly and directly asked the following questions:

- (1) Are consumers and the market seriously disadvantaged by denial of full access to interoperability information? If the answer is "yes":
- (2) Would the respondent and the market be seriously disadvantaged by a duty to grant access?

According to the facts on file, it seems that first answer would indeed have been positive (in the Court's decision, it is repeatedly mentioned that users preferred certain rivals' products on all qualities except interoperability) and the second one negative (it should again be remembered that, according to the facts, before achieving a significant presence in the market of server OSs, Microsoft provided complete interoperability information).

A similar exercise – but with probably a more uncertain outcome – could be carried out for bundling (see Andreangeli 2010). In brief, one could ask whether, through the bundling of the Windows Media Player with Windows, consumers

were really “coerced” to use Windows Media Player and, as a result, consumers (and competitors) were harmed by this conduct.

The relativity of competition conceptions, and the ensuing flexibility of antitrust laws, and in particular the regulation of unilateral behavior (the most flexible of them all), becomes especially apparent if a parallel is made between how the EU dealt with the conduct of Microsoft and how the US treated it – or, better, would treat it. This is particularly apparent with respect to the interoperability issue and to the imposition, via antitrust laws, of the duty to supply. As Fox (2010) again shows:

Any analyst applying the law and spirit of *Trinko* [landmark decision where the US Supreme Court emphatically underlined that there is no duty to deal in American antitrust law] would not start the analysis with the question posed above: Are consumers seriously disadvantaged by work group suppliers’ lack of seamless access to the standard operating-system network? Analysis would start with quite a different question: Why should Microsoft be ordered to share its property with anyone, let alone rivals? US courts generally presume that a duty to deal will seriously impair a monopoly firm’s incentives – to the harm of the market and innovation.

A similar conclusion on the EU-US divide can be taken for the claim of illegal bundling. As shown by the Court of Appeals of DC in the US Microsoft case, US Courts do require a rule or reason assessment and, in so doing, set the threshold pretty high before concluding that bundling is anticompetitive in a new economy setting (see Andreangeli 2010).

Implications for the Future

Many have highlighted the true exceptionality of the facts of the Microsoft case, which would suggest that it is difficult to draw any lessons for the future. Still, we believe, two main implications can be detected.

Microsoft was the first in a new string of cases dealing with the new economy and forcing antitrust laws, which in decades had developed with more traditional industries, to be confronted with extremely difficult questions. More than ever

economic and technical knowledge are essential. Current (at the time of writing) investigations like *Google* raise important questions on the definition of the relevant markets and of abuse in highly complex and interconnected market (see Pollock 2010; Lianos and Motchenkova 2012; Bork and Sidak 2012).

Secondly, it has been noted above that the EU has taken a “typically European” approach, which in the end is definitely more interventionist as compared to the US one. One may wonder whether this will continue in other new economy cases or whether a rapprochement with what happens across the Atlantic can be expected.

Eucken, Walter

Stefan Kolev

Wilhelm Röpke Institute, Erfurt and University of Applied Sciences Zwickau, Zwickau, Germany

Abstract

The purpose of this entry is to delineate the political economy of Walter Eucken. To reach this goal, a history of economics approach is harnessed. First, the entry concisely reconstructs Eucken's life, intellectual evolution, and heritage. Second, it presents the specificities of his "theory of orders" and his "order-based policy" gateway to a rule-based political economy.

Biography

Walter Eucken (1891–1950) was doubtlessly one of Germany's most important twentieth-century economists, especially in the field of political economy. The Freiburg School, which he co-initiated in the 1930s as an interdisciplinary group of economists and legal scholars, has had a crucial impact on the evolution of postwar German economics and legal scholarship, but also on the practical trajectory in the economic policies of the Federal Republic and of European integration. This introduction aims at embedding Eucken in his time and at depicting his role in several contexts in science as well as at the interface between science and society, before subsequently turning to his contributions to political economy.

Eucken was born in Jena into the family of the philosopher and later Nobel Prize laureate Rudolf Eucken. He studied a combination of history, economics, law, and administrative science at Kiel, Bonn, and Jena and was heavily influenced in his socialization in economics by the Younger Historical School, even though his teachers were not totally hostile to theorizing (Goldschmidt 2013, pp. 127–129). Having completed a dissertation (at Bonn) and a habilitation (at Berlin) on historicist grounds, he received a call to Tübingen in 1925 and subsequently to Freiburg in 1927, where he remained for the rest of his life. What would later become famous as the Freiburg School of Ordoliberalism came into existence in the early 1930s, when Eucken formed a scholarly community with the law professors Franz Böhm (1895–1977) and Hans Großmann-Doerth (1894–1944), also attracting talented younger scholars like Friedrich Lutz (1901–1975) and Leonhard Miksch (1901–1950) to Freiburg (Goldschmidt and Wohlgemuth 2008a). The cooperation of Eucken with Böhm and Großmann-Doerth steadily intensified, with the book series "Order of the Economy" initiated in 1936 as a milestone – its introduction under the title "Our Mission" became the programmatic manifesto of the incipient ordoliberal understanding of the role of law and economics in science and in society (Böhm et al. 2008; Goldschmidt

and Wohlgemuth 2008c). In the adverse intellectual climate of the time, Eucken and Böhm actively rejected National Socialism in theory and in practice, with Eucken openly opposing Martin Heidegger's rectorate policies in the university senate in 1933 (Nicholls 1994, pp. 60–67; Klinckowstroem 2000, pp. 85–88). Eucken was also among the very few who remained openly loyal to Edmund Husserl until his death in 1938, with his own epistemology heavily influenced by Husserl's phenomenology. Also, in the late 1930s and early 1940s, Eucken was an active participant in intellectual resistance groups, later to become known as the Freiburg Circles (Glossner 2010, pp. 31–38). Despite the isolation particularly during the war, Eucken remained connected to intellectual allies like F.A. Hayek and Wilhelm Röpke and in the immediate postwar years became a seminal figure in the international revitalization of liberalism, among others during the founding years of the Mont Pèlerin Society (Kolev et al. 2014). Simultaneously, Eucken was one of the principal policy advisors to the allies in Germany and also to Ludwig Erhard's increasingly influential policy strategy, later to become famous as the Social Market Economy (Goldschmidt and Wohlgemuth 2008b, pp. 262–264; White 2012, pp. 233–238). Eucken passed away in March 1950 while giving a lecture series at the London School of Economics upon Hayek's invitation.

While the relevance of ordoliberalism for post-war Germany and Europe is discussed in the entry dedicated to ordoliberalism, the impact of Eucken's heritage as a person deserves special attention. In 1954, the Walter Eucken Institute was founded by friends, colleagues, and students in the house of his family in Freiburg and is until today an influential research institute and think tank. Eucken's personality still attracts paramount attention: in 2014 Federal President Gauck delivered an address in Freiburg upon the 60th anniversary of the Walter Eucken Institut, in 2016 Chancellor Merkel delivered an address in Freiburg upon Eucken's 125th birthday, while today's economists argue about "Walter Eucken's long shadow" in the German policy responses to the Euro crisis (Feld et al. 2015; Bofinger 2016) and

his relevance for related rule-based research programs like Constitutional Political Economy (Vanberg 1988; Buchanan 2012; Köhler and Kolev 2013).

Order, Science, and Policy

As described above, Eucken lived in a time as hostile as possible to liberty – and in a time which was characterized by extreme degrees of arbitrariness and chaos. This is one of the reasons why Eucken and his associates focused their political economy and social philosophy on the concept of "order" – a term which is among the most complex and most multifaceted in intellectual history (Anter 2007, pp. 127–158). Eucken's specific research program took shape relatively late in his life – it "matured slowly" (Hayek 1951, p. 337) – and can be interpreted as concentrating upon two central goals: first to enable a higher degree of order for designing economic theory and second to enable a higher degree of order for conducting economy policy. These two goals are also the focal points of two key terms in Eucken's system and of his two major books: *Ordnungstheorie* as his contribution to economic theory, presented 1940 in *The Foundations of Economics* (1992), and *Ordnungspolitik* as his contribution to economic policy, presented 1952 in his posthumous *Principles of Economic Policy* (2004). Important to underscore and to show below, both Eucken's theory and his perspective on economic policy are very much in line with the "problem of constitutional choice, i.e., as a question of how desirable economic order can be generated by creating an appropriate economic constitution" (Vanberg 2001, p. 40). The two domains of theory and policy offer a helpful structure for continuing this exposition.

Theory of Orders: An Alternative to the Ruins of Historicism and Pure Abstraction

German economics has been famous, and at times notorious, for its inclination toward extensive methodological and epistemological debates.

The notoriety stems from periods like the Weimar Republic, when many economists continued fighting about methods and epistemology without being able (or willing) to tackle the pressing problems of economic life (Köster 2011, pp. 41–60). Eucken's project was targeted at the very opposite: with his "Foundations" he attempted to identify a solid methodological and epistemological basis for theorizing not as an aim in itself, but rather to enable such kind of theorizing which can alleviate the immense problems of the age after National Socialism. This section focuses on those theoretical concepts that have direct practical impact and are thus indispensable for understanding Eucken's political economy.

First and foremost, the separation between "order" and "process" is crucial: "economic order" for Eucken is to be understood as the sum of market forms and monetary systems which frame the interactions of the individuals, whereas "economic process" stands for the interactions themselves. Synonymous for the framework of the economic order are "the rules of the game," whereas the economic process can be translated as "the moves of the game" (Eucken 1992, pp. 223–232, 2004, p. 54). An additional cornerstone of Eucken's system is "the interdependence of orders" – a concept emphasizing the embeddedness of the economic order within the other social orders, notably the law and the political order of the state. This is of special relevance since it shows that even though the different social orders have their own individual logics, these orders have to be thought in their diverse interrelations. Also, the combinability of economic, legal, and political orders is not arbitrary, i.e., specific combinations like a centrally planned economy and rule of law are hardly stable in the long term. At the same time, he underscored that having a well-developed rule of law is not a sufficient condition for a well-ordered market economy – rather, it is through the cooperation of economists and legal scholars that specific principles of the rule of law will be identified as indispensable preconditions and prerequisites for the market economy (Eucken 1992, pp. 85–90). Eucken's theory of orders thus made

it possible to do away with the ruins of atheoretical or even antitheoretical historicism left by the Younger and the Youngest Historical Schools well into the 1930s, but at the same time he warned that abstract theorizing can be dangerous if its results are applied to any orders without carefully considering their specificities of time and space (Eucken 1992, pp. 41–44).

Order-Based Policy: An Alternative to Laissez-Faire, Central Planning, and Interventionism

The careful and systematic shaping of the economic order (synonymously: of the economic constitution) is at the core of Eucken's political economy. The above theoretical distinction of "order" and "process" enabled him to coin his famous *Ordnungspolitik*. A term difficult to translate precisely into any other language, it has been translated into English with the general term "rule-based policy" or with the more specific one "order-based policy." Its central target is a clear-cut conceptual alternative to laissez-faire, to the centrally planned economy, and to interventionism, using two criteria which Eucken distilled as essential for judging the merits of economic orders: the material criterion if an order is productive (i.e., overcoming scarcity as much as possible), and the ideal criterion if an order is humane (i.e., enabling a life in self-determination for the individuals) (Eucken 1992, pp. 239–241). Neither a laissez-faire regime nor a centrally planned economy fulfill these two criteria – a laissez-faire regime is deficient in terms of the framework of its economic order (with the implied belief in its automatic self-generation), while a centrally planned economy is deficient in terms of the properties of its economic process (and the impossibility of a self-determined life in it) (Eucken 1948). Eucken's "order-based policy" aims at optimally setting the rule-based framework of its economic order by a strong state envisioned as a referee impartial vis-à-vis vested interests, a state which (unlike the arbitrariness of interventionism) abstains from interventions into the economic

process except in well-defined exceptions (Giersch et al. 1992, pp. 28–32). Such a policy is aimed at fighting the first and foremost evil of social life: according to the Freiburg School, this evil is always the phenomenon of power in all forms of power relations – stemming from the state, from the market, and from other social orders (Eucken 2004, pp. 175–179; Foucault 2008, pp. 129–158). As first presented by Böhm and discussed in the entry covering his work, the ordoliberal instrument against power is competition. Eucken’s contribution here is to specify the kind of principles a “competitive order” – the order conforming both to the “productive” and to the “humane” criterion – has to follow (Oliver 1960, pp. 133–140). He devised two sets of principles, which are at the core of this “competitive order”: the “constitutive” and “regulating” principles. The former comprise a functioning price system, a sound currency, open markets, private property, freedom of contract, liability, and constancy of economic policy, while the latter aim at additionally curbing monopoly power, income inequalities, externalities, and problems of the labor market (Sally 1998, pp. 111–114; Kolev 2015, pp. 428–430).

Many of these problems may seem almost trivial today, but at the time of Eucken’s death, they were anything but trivial – not in Europe and not in the United States, as the parallels between Eucken’s endeavor and the project of the “Old Chicago” School clearly indicate (Van Horn 2009; Buchanan 2012; Köhler and Kolev 2013). Other problems, especially the issues of power in the digital age, the lack of liability in large sections of the political order and the financial system, or the search for maxims how to avoid the arbitrariness of interventionism and instead to base economic policy on rules, have lost nothing of their relevance.

²International and European Union Law, Erasmus University Rotterdam, Rotterdam, The Netherlands

Abstract

European Community law has evolved over the last 60 years as a process of European economic integration. European law has developed alongside the stages of economic integration in a reciprocal process, with euro-area Member States being close to total economic integration. However, economic integration has not been unhalted – political and economic realities have forced the EU to adapt to current developments and negotiate treaty amendments but sometimes also to act outside the Treaty framework. Other influences, such as interest groups, have also shaped the dynamics of interest groups.

Synonyms

[European law](#); [European Union law](#)

Definition

European community law consists of the law that is found in the Treaty on European Union (TEU) and the Treaty on the Functioning of the European Union (TFEU). In addition European community law comprises regulations, directives, or decisions, as well as the soft-law form of recommendations and opinions.

The Legal Framework of the European Union

Introduction: The History of Integration and Main Legal Texts

The European Union (EU) as we know it today is a result of a process of European integration that

has lasted for the most part of the last seven decades. While this might seem like a long time, it is only a blink of an eye in the overall history of the European continent.

The European Union has evolved from what was earlier called the European Community, which in turn was based on three communities founded in 1951 (the European Coal and Steel Community (ECSC)) and more importantly in 1957 (the European Economic Community (EEC) and the European Atomic Energy Community (EURATOM)) by means of the treaties of Paris and Rome, respectively (Lenaerts and van Nuffel 2011). While the Treaty on the Coal and Steel Community was concluded for 50 years only, the Communities as of 1957 were entered into for an unlimited period (art. 356 TFEU). Six Member States, Belgium, France, Germany, Italy, Luxembourg, and the Netherlands, committed themselves to the process of economic integration and gave away sovereign rights to a supranational order. They agreed to have some policy areas governed by four principal institutions: The Council as a representation of Member States, the Commission (or at that time the High Authority), the Assembly (later to be the European Parliament), and the Court. The Council and the Commission were triplicated for all three communities but joint for the purposes of efficiency and convenience by the Merger Treaty in 1965 (Craig and De Burca 2011; Hartley 2014; Lenaerts and van Nuffel 2011).

While the ECSC Treaty was very specific as regards the policy to be pursued by the institutions, the EEC treaty left much more leeway to the institutions to fill in their objectives. In addition, the mainly economic aims of the Communities were complemented by ideas of a political, social, and cultural union. Probably the greatest step for the Communities was the establishment of the European Union by the Maastricht Treaty in 1992, which also paved the way for the Economic and Monetary Union (Hartley 2014). This treaty was founded on the communities and introduced two more policy domains to be dealt with by cooperation: a common foreign and security policy and cooperation in the field of justice and home affairs (Craig and de Burca 2011).

However, the process of European integration did not only concern the deepening of integration but also the widening. Membership became open for other States in Europe: Even though the UK was initially reluctant to join the EU, it ended up applying for membership, first blocked by Charles de Gaulle but later realized in a group accession including Ireland, Denmark, and Norway in 1972. In the years 1979 and 1981, Greece, Spain, and Portugal joined, before some of the EFTA countries, Sweden, Finland, and Austria, acceded to the Union in 1994. The biggest accession process, however, concerned a group of former communist countries in the East of Europe (Lithuania, Latvia, Estonia, Poland, the Czech Republic, Slovakia, Hungary, Slovenia) and two Mediterranean islands, Cyprus and Malta (Nugent 2010). More recently, Bulgaria and Romania have joined and the currently last Member to the EU is Croatia, which acceded in July 2013 (Hartley 2014).

The Treaty of Lisbon, a result of the failed constitutional treaty for the European Union, replaced the European Community by the European Union as the sole entity and led to a deepening of the EU competences and codified institutional developments in the Union (Craig and de Burca 2011).

European Union Law as a Body of Law

Status of European Union Law and Main Legal Texts

The law of the European Union can roughly be divided into primary and secondary legislation. Primary law is the law that is found in the treaties, the Treaty on European Union (TEU) and the Treaty on the Functioning of the European Union (TFEU). The TFEU superseded the Treaty on the European Community as a result of the Treaty of Lisbon (Fairhurst 2012).

Secondary law is EU law that is adopted on the basis of primary law, the so-called legal bases, and can take the shape of regulations, directives, or decisions, as well as the soft-law form of recommendations and opinions (art.288 TFEU). Regulations have general application and are binding in their entirety, while directives are binding as to the result to be achieved (and need to be implemented by national authorities); however, Member States

are free to choose form and methods. Decisions are binding in their entirety on those to whom they are addressed. If there is no legal basis in the treaty, the EU is not allowed to adopt any legislation; this is called the principle of conferral as laid down in art.4 (1) and art.5 (1) TEU (Craig and de Burca 2011). Those areas in which the Union is allowed to legislate are divided in three categories:

Exclusive competence areas are those on which only the Union is allowed to legislate, the customs union, competition rules, monetary policy for euro-area Member States, conservation of marine resources under the common fisheries policy, and the common commercial policy (art.3(1) TFEU). This competence also applies in external context for the negotiation of international treaties, which the Commission is allowed to sign on behalf of the EU for these policy areas (art.3(2) TFEU).

Shared competence areas are those in which both the Union and its Member States are allowed to take legislative action and include the social policy; economic, social, and territorial cohesion; and transport (art.4(2) TFEU includes a full list). However, the level on which decisions are actually taken is governed by two important principles of the EU: subsidiarity and proportionality (Lenaerts and van Nuffel 2011). Both principles were put in the Treaty of Maastricht (TEU) and describe that:

Under the principle of subsidiarity, in areas which do not fall under the exclusive competence of the Union, the Union shall act only if and in so far as the objectives of the proposed action cannot be sufficiently achieved by the Member States, either at central level or at regional and local level, but can rather, by reason of the scale or effects of the proposed action, be better achieved at Union level (art.5(3) TEU)

and

under the principle of proportionality, the content and form of Union action shall not exceed what is necessary to achieve the objectives of the Treaties. (art.5(4) TEU)

There is one competence that is the odd one out – economic coordination. While monetary policy is an exclusive competence of the EU and

is conducted by the independent European Central Bank, Member States are to “coordinate their economic policies within the Union” (art.5(1) TFEU). This discrepancy in competence division is arguably one of the reasons for the euro crisis (de Grauwe 2012).

Not only can one categorize European Law on the basis of competences, another divide that is often made is the distinction between Internal Market law and institutional/constitutional law (see below). The notion Internal Market describes a Common Market between the members of the EU. While economic integration was initially the main purpose of the Union, the institutional setting has only evolved alongside the process of integration.

The Institutions

After the Treaty of Lisbon, the European Union is officially governed by seven institutions: the European Parliament, the European Council, the Council, the Commission, the Court of Justice of the European Union, the European Central Bank, and the Court of Auditors (art.13 TEU). These institutions have developed over time, although most of them were part of the Union framework even before they were officially mentioned as institution in the treaty. However, some institutional developments cannot go unmentioned (Hartley 2014).

The European Parliament used to be called the Assembly until 1962 (EP Resolution of 30 March 1962, JO1962) and hardly had any powers at all in decision-making – it was not even recognized as an institution. That changed in the case *European Parliament v. Council* Case 302/87 (1988) ECR 5615 concerning the Parliament’s legal standing in front of the Court, which, before the judgment, was not “privileged,” i.e. directly admissible with any action before the Court, a prerogative reserved for institutions (Hartley 2014). The European Parliament then started to play an ever greater role in the EU, culminating in the first direct elections for the European Parliament in 1979, and together with the national parliaments, it is now seen as the democratic underpinning of the European Union. It is comprised of currently 751 members representing the European people

by degressively proportionate representation, with a slight overrepresentation of small Member States.

More recently, the introduction of the so-called ordinary legislative procedure by the Treaty of Lisbon basically made the European Parliament co-legislator with the Council in most areas of European law (art. 294 TFEU). The Council, as the main legislator, is comprised of ministerial delegates who are authorized to commit their governments (art. 16(2) TEU); the Council does not have a fixed constellation, but the ministerial delegates will change depending on the topic to be discussed – finance ministers will legislate on financial matters, ministers of agriculture will legislate on agriculture, etc. The presidency of the Council rotates on a half-year basis among Member States; however the situation is different when it comes to a, one could call, special configuration of the Council, the European Council. The European Council is comprised of the Member States' heads of state or government and has, since the Treaty of Lisbon, a permanent president who is elected for two and half years. The European Council is the highest political organ of the European Union and provides it with the necessary impetus for its development and defines general political directions and priorities (art. 15 TEU; Craig and de Burca 2011). Especially in the euro crisis, the European Council has played a major role with regard to the measures taken to tackle the crisis, since the situation required a consensus on highest political level.

The Commission is an independent body representing the Union interest and is led by 28 Commissioners, one from each Member State. Commissioners are proposed by the European Council, while the European Parliament has to consent to the appointment of the president of the Commission and his or her Commissioners by the European Council (art. 17(5) TEU). The Commission is the only institution to have legislative initiative; it formulates proposals for new EU policies, mediates between Member States, and oversees the execution of Union policies. It could be regarded as the EU executive (Craig and de Burca 2011).

The European Central Bank (Hartley 2014, p. 31f) only became an official institution once the Treaty of Lisbon entered into force, even though it existed in the same shape before – since the inception of the Economic and Monetary Union (EMU). Its independence in conducting monetary policy for the Member States whose currency is the euro is enshrined in the treaty (art. 283(3) TFEU) and is only limited by its mandate being that of securing price stability (art. 127(1) TFEU).

The Court of Auditors consists of one national per Member State from within a pool of national auditors. Their task is to examine the accounts of revenue and expenditure of the European Union and to provide the Union legislator with reports on the regularity and legality of such (Hartley 2014, p. 31). The Court of Auditors is strictly a monitoring institution and is not to be confused with the Court of Justice of the European Union (CJEU). The CJEU has, in the context of the reforms of the Lisbon Treaty, undergone a major restructuring and is now divided in the General Court (a court of first instance and for the less difficult cases), the European Court of Justice (for seminal cases, it always sits in full court), and the Civil Service Tribunal (for cases involving the staff of the EU). The Court of Justice has played a major role in the process of European integration (Craig and de Burca 2011), which will be discussed below.

In general, however, the division of tasks among the institutions in the European Union is very well thought through and quite balanced. The Commission, together with national authorities represented in the European Council, acts as an executive; the Council and the Parliament now share the legislative competence, while the CJEU is the obvious judiciary. The European Central Bank is probably the only central bank whose independence is enshrined in a document of arguably constitutional value (the treaty). The democratic legitimacy of the European Union is based on the European Parliament and the indirect control that national parliaments have on their governments when they take decisions in the Council, as well as the principle of subsidiarity which is controlled by national parliaments (Lenaerts and van Nuffel 2011).

While the establishment of a democratic Union is one of the proclaimed aims of the EU, one has to be aware of a debate that has mainly started with the Treaty on European Union in Maastricht and that deals with the question of a democratic deficit in the European Union. Two strands of literature claim the existence of such a deficit. First, institutionally speaking, the European Parliament is argued to be unrepresentative of the European people since voter turnout is relatively low and the ordinary legislative procedure is not applicable in important policy areas such as the Common Foreign and Security Policy and the monetary policy. In addition, the involvement of national parliaments is often seen as too little (Follesdal and Hix 2005). Second, a sociopsychological democratic deficit is often attested for the Union. This refers to the lack of a common European people (demos), which in turn leads to a conceptual lack of a European democracy. Opponents on the other hand argue that there is no democratic deficit, because the Union is mainly a technocratic order and is also designed as such (Majone 1998). While this debate is worthwhile exploring, it would go beyond the scope of this entry to discuss it in detail.

European Union Law as a Legal Order

The treaties are essentially treaties that have been entered into under the rules of public international law. However, the European Union legal order has evolved as a legal order standing on its own. In this, the European Court of Justice has played a major role in the early years of integration. Two seminal cases defined the status of European Union law. First, in the case *Van Gend en Loos v Nederlandse Administratie der Belastingen* (1963) Case 26/62, which concerned a reclassification of a chemical in another customs category by the Benelux countries, the Court stated that the EEC Treaty was a legal order on its own, capable of creating legal rights which can be enforced directly by natural or legal persons before the courts of the Community's Member States, if the respective provision was "clear, precise, and unconditional." This principle is now called the principle of direct effect and is probably one of the most important principles of Union law

and has been further developed (Craig and de Burca 2011).

Another seminal case that thrived European integration is the case *Flaminio Costa v ENEL* [1964] ECR 585 (6/64) which regarded an alleged incompatibility of an Italian domestic law with the treaty. Here, the Court stated that "the law stemming from the treaty, an independent source of law, could not (...) be overridden by domestic legal provisions, (...), without being deprived of its character as community law and without the legal basis of the community itself being called into question." It thereby effectively established supremacy of the Union law over national law, which even applies in the case of national constitutions (*Internationale Handelsgesellschaft und Vorratsstelle für Getreide und Futtermittel* Case 11-70, ECR 1970 1125; Lenaerts and van Nuffel 2011).

The Dynamics of the European Union Law

The legal order of the EU has not only changed and developed because of the proactive Court of Justice. Rather, the EU has always reacted to social, economic, and political realities and has changed accordingly. Unfortunately, this has not always been to the benefit of a more coherent EU law. In order to change the treaties and provide the Union with more competences, all Member States have to be in agreement (art. 47 TEU) and ratification in all Member States is required. Increasingly, the Member States find it hard to reach consensus among, currently, 28. Some Member States are keen to drive the integration process forward towards a political and social union, while others are more reluctant. In some policy areas, therefore, some Member States have negotiated an opt out (such as the UK and Denmark regarding the monetary union) or those Member States that wanted to further integrate opted for different (intergovernmental) solutions (Craig and de Burca 2011).

The Schengen Treaty is one example of such further cooperation which started out as an international treaty outside the EU framework. Some Member States committed themselves to abolish border controls among themselves in order to facilitate the free movement of persons. Later,

however, the Schengen Treaty was incorporated into the EU treaty framework and is now part of the so-called *acquis communautaire*, the Union law that needs to be accepted and implemented by all new Member States. Only those Member States that did not ratify the Schengen Treaty before it was part of the Union framework (the UK and Ireland) are not obliged to comply with Schengen (Hartley 2014).

Similar developments have taken place with regard to the tackling of the economic and debt crisis. While EU measures enhancing the economic agreements under the so-called Stability and Growth Pact (SGP) have been adopted and implemented in the form of the six pack (six regulations and one directive) and the two pack (two regulations), agreement on the establishment of a permanent financial stability mechanism could not be reached. In addition, mechanisms for immediate financial assistance for Member States in case of an economic crisis were not foreseen in the treaty. The result was the establishment of somewhat hybrid institutions such as the European Financial Stability Facility, a *societe anonieme* under Luxembourg law backed up by euro-area Member States lending money to other euro-area Member States in financial trouble, the granting of bilateral loans to Greece, and the European Financial Stability Mechanism, all of which are now replaced by the permanent European Stability Mechanism, the ESM (de Grauwe 2012). The ESM as well is founded in a treaty outside the EU framework ratified by 25 Member States (apart from the Czech Republic, the UK, and Croatia), although a treaty change to art.136 TFEU has been made allowing the euro-area Member States to establish among themselves a European Stability Mechanism. Another inter-governmental treaty, the Treaty on Stability, Coordination, and Governance (TSCG), has been ratified by the same countries, in order to improve fiscal discipline and economic coordination among the signatories. Both treaties are designed to include the EU institutions such as the Commission and the Court in their working, and the EU aims to incorporate these treaties in the EU framework midterm. However, it is striking that intergovernmental decision-making in the context

of treaties or the European Council has gained momentum in recent years. While it used to be the aim to bring more and more policy areas under the supranational pillar of decision-making (the ordinary legislative procedure), particularly the economic and monetary union is increasingly governed intergovernmentally. The European Council might be evolving from an institution that gives political impetus to an institution with a more legislative role. While this might arguably sidestep the European Parliament, it is also an example for the dynamics of EU institutional law. The mode of decision-making seems to increasingly depend on the sensitivity of the policy area concerned: Internal Market law on the other hand is still a prime example for supranational decision-making in the EU.

The Co-development of European Community Law and Economic Integration

The Economic Rationale for European Community Law and Integration

The body of European Community law implies a great promise for the European Member States, companies, and citizens. Tearing down barriers to trade and closer institutional integration can reap considerable welfare gains.

Even though the beneficial effects of free trade are known since the works of Adam Smith (1776) and David Ricardo (1817), it was the Cecchini-report from 1988 (Cecchini Report 1988) that estimated an overall cost reduction of 200 billion ECU for the Member States, if all trade barriers (tariff and non-tariff) would fall. However, the report provided no detailed analysis about the growth effects and distributional consequences for and between regions (e.g., center and periphery) (Baldwin 1989).

Because some Member States win and some lose with regard to their absolute welfare position, when trade barriers are removed (while overall welfare increases), it did not come as a surprise that in the aftermath of the Cecchini-report, the potentially losing Member States resisted a simple

abolishment of trade barriers (for a theoretical analysis, see Pierson 1996).

The insight that the distributional consequences of abolishing trade barriers which must be taken into account leads to three basic propositions that drive the economic analysis with regard to European Community law.

1. Economic integration is a process in time in which the Member States go through *stages of integration*, thereby deepening integration.
2. European Community law is mirroring the stages of integration, thereby aiming towards a European *constitution*.
3. At the micro-level the integration process is driven by *interest groups* and stakeholders that impact on the content of European Community law.

Stages of Integration

It is common to differentiate five generic stages of economic integration (Balassa 1961; Baldwin and Wyplosz 2012). Economic integration usually starts at the first or second stage and progresses then over time towards stages of higher integration.

1. The first stage is mainly associated with a bilateral or multilateral free trade agreement (FTA) between countries. While the abandoning of tariffs between the signatories of the FTA reaps some welfare gains, running an FTA is not trivial and not easily administered. That is because of the FTA countries' freedom to determine the tariff with third countries on their own. For importers and FTA countries alike, this creates opportunities for arbitrage (Tarr 2009). As a consequence rules of origin have to be introduced and maintained. One may conceive these rules of origin as a very nascent step into the direction of a common understanding over the rules of the game between FTA countries. One may regard this as a first step towards a premature constitution.
2. The second stage is the customs union (CU). The signatories of a CU abandon tariffs against each other, but they also agree on a common tariff against third countries. This overcomes

the problem of maintaining and controlling complex rules of origins as it is necessary under an FTA. From an economic perspective, the Treaty of Rome (1957) constituted a CU.

3. The third stage is the establishment of a common market (CM). The Treaty of Rome implied already the antecedents of a CM, although it took time till the 1980s to establish and enforce the features of a CM. Central to a CM is that non-tariff barriers to trade (national regulations) which impede trade become removed and that the free movement of people/companies, services, and capital becomes feasible. Two features of a CM need special attention: First, non-tariff barriers for goods, people/companies, services, and capital (four freedoms) can either be overcome by harmonizing laws and regulations or by mutual recognition of laws and regulations. Both ways play out in the European economic integration process. Second, to safeguard the four freedoms, a CM has to establish a common competition policy, preventing the Member States to give unfair advantages to their industries (esp. state aid control). Both features have in common that they need policy coordination between Member States, implying that there is a basic agreement about the vertical delineation of the competencies between the central level (EU level) and the signatories (Member States). In parallel power has to be vested to institutions and administrations at the central level, in order to execute the common policies. This process of institutionalization becomes apparent, for example, in the increasing role that the Court of Justice of the European Union plays.
4. The fourth stage is the economic union (EUN), which is a CM where a number of key policy areas are harmonized (esp. coordination of monetary and fiscal policies, labor market, regional development, infrastructure, and industrial policy). While at the first three stages of economic integration the removal of obstacles to free trade are center stage (negative integration), at the fourth stage the particular institutional design of the economically integrated area becomes important. This process of

institutionalization goes hand in hand with the strengthening of administrative bodies managing for the particular design of integration (positive integration). However, the implementation and enforcement of policies remain with the associated countries. The establishment of the European Single Market (Maastricht Treaty) is a good example of a EUN.

5. The fifth stage is total economic integration (TEI). At this stage, a vast number of key policies become harmonized, *inter alia* those as social policy and monetary and fiscal policy. A TEI exploits all possible economic advantages from free trade and factor mobility. The momentum of positive integration becomes amplified by shifting even more power to the central administration. The policies from the central level become binding for the associated countries, which role is only to execute the prescribed policies from the central level. The EU has yet not reached the stage of TEI, but the members of the euro area are close to it.

Towards a European Constitution

European Community law has yet not been consolidated in a European constitution. The “Treaty establishing a Constitution for Europe” from 2004 was not ratified by all Member States; as a consequence in 2005, the project of a European constitution was given up. Instead in 2009 the Treaty of Lisbon implemented parts of the constitutional project (e.g., qualified majority voting) through the established European treaties.

Insofar, in a strict legal sense, European Community law has yet not reached the status of a constitution. However, European Community law has undoubtedly evolved over time towards a tighter set of rules and regulations (institutional integration). From a law and economics perspective, the crucial question is whether the institutional integration of the EU corresponds indeed with more transborder transactions and hence more gains from trade. In other words, does the process of European constitutionalization lead to welfare gains?

This question can only be answered empirically and it bears the question of how to measure institutional integration. However, Mongelli

et al. (2005) can show that a higher degree of institutional integration goes hand in hand with more economic integration (trade). Thereby it seems that causation runs both ways: More institutional integration triggers more economic integration, but more economic integration also leads to more institutional integration. From that observation follows that there is a coevolution between European Community law and economic integration. This implies that the European constitutionalization process is driven by policy choices for the background of a deepening economic integration, while at the same time the deepening of economic integration depends on the policy choices that were made.

The Role of Interest Groups

European Community law is the product of actors on the national and the EU level which try to shape the governing rules and the law-making process into a for them favorable direction. Usually those actors are labeled as interest groups. Even though the term “interest groups” must not have a negative connotation but can refer to quite a lot of meanings in the process of European integration (Eising 2008), from an economics perspective it refers mainly to well-organized groups that try to get an economic advantage that is not the result of their economic performance but of their successful attempts to get favors via the political process (rent seeking) (Mueller 2003; with special reference to federations, see Weingast 1995). For example, the persistent high levels of subsidies that go into the common agricultural policy (CAP) can only be explained by the influence that the interest group of farmers has on European politics (Baldwin and Wyplosz 2012).

The role of interest groups in the process of European integration in general and the impact of interest groups on European Community law in particular can be studied from a great number of perspectives (for an overview, see Eising 2008). From a law and economics perspective, it is important to understand the making of European Community law as the result of a coevolutionary process of diverse interest groups, which influence laws and regulations, and the body of European law, which creates the forum in which

interest groups and stakeholders can play out. Thereby the European Community law becomes over time more differentiated and adapted to the challenges it faces in an ever more economically integrated area, but at the same time the increasing complexity of European Community law creates gaps and loopholes that can be targeted by interest groups. This implies on the one hand that interest groups have to evolve to organizations that are able to target those loopholes and gaps. On the other hand, it implies that Community law reacts to the activities of interest groups with a further differentiation of law and regulations.

While the relevance of interest groups for the development of European institutions and Community law cannot be doubted, the operation of interest groups in the EU is yet not fully understood. For example, it is yet not clear whether there is a Europeanization of interest groups (making the level of Member States less important) or whether successful interest groups on the European level need a strong anchoring in the Member States. Moreover, one may ask whether the specific politico-legal system of a Member State predetermines the effectiveness of interest groups on the European level (Eising 2008).

European Court of Human Rights

Federica Gerbaldo

IEL- Institutions, Economics and Law, Collegio Carlo Alberto, University of Torino, Turin, Italy

Abstract

The European Court of Human Rights is a Supra-national Court established in 1959 with the European Convention on Human Rights. It stands as a monitoring mechanism to ensure the observance of the commitments to ensure fundamental human rights undertaken signing the Convention.

This entry focuses on the functioning mechanism of the Court either from a prescriptive and an empirical point of view. The first aspect

concerns organization and procedural issues, with special regard to the sanctioning mechanism, whereas the second aspect involves issues of effectiveness of the Court.

Definition

The European Court of Human Rights (ECtHR) is a supranational court founded by the European Convention of Human Rights (ECHR) in 1959 and based in Strasbourg (France). It carries out a supervisory function monitoring that the 47 member states of the Council of Europe (COE) that have ratified the Convention comply with its substantive provisions. The court fulfills its task scrutinizing claims alleging that the defendant state breached its commitment violating one or more ECHR provisions.

History

Founded in 1949, the Council of Europe (COE) became the very first political organization in Europe, although its approach was different from the European institutions. In the era of reconstruction after World War II, the original member states chose the path of cooperation and signed the founding treaty of COE as a reaction to the atrocities of the war and the growth of East-West tension. States parties made efforts in strengthening cooperation, signing international treaties, publishing peer reviews, exercising pressure, and promoting training and good practice; reinforcing citizenship and democratic governance was the ultimate goal.

The ambitious project of *achieving a greater unity between its members for the purpose of safeguarding and realizing economic and social progress* (article 1 Statute of council of Europe, 1949. Add to documents references Council of Europe, Statute of the council of Europe, 05 May 1949) aimed to guarantee lasting peace and prosperity on a continental scale. In this sense, the most successful achievement is the ECHR signed in 1950 and entered into force in 1953 and the creation of a monitoring mechanism with the

establishment of ECtHR. As a response to the inertia of the United Nations and its inconclusive attempts to transmit the principles proclaimed in the 1948 Universal Declaration of Human Rights into an internationally binding bill of rights, some of the Western European countries egged on the COE to proceed on its own. Thanks to the obduracy of those countries that share *a common heritage of political tradition, ideals, freedom and the rule of law* (European Convention of Human Rights, preamble, 4th November 1950, 213 UNTS, 221), the COE took the first steps for the collective enforcement of some of the human rights stated in the Universal Declaration.

Even though ECHR scope is more specific, the Convention arranges one of the strongest regional mechanisms for protection of fundamental individual human rights and stands as a model for other regional systems (Buergetal 2006). Signing the Convention, high contracting parties undertake to grant to every individual within their jurisdiction civil liberties typical of an effective political democracy. Among others, the Convention grants life, fair hearings, private and family life, freedom of expression, freedom of thought, conscience and religion, and property rights and prohibits torture or inhuman treatment, slavery and forced labor, arbitrary and unlawful detention, and discrimination. Besides the declaration of a list of human rights that contracting states commit to recognize and grant (see Harris et al. 2014 for an analysis of the rights granted), the Convention made protection effective establishing a monitoring mechanism to *ensure the observance of the engagement undertaking by the high contracting parties* and providing remedies for victims of violations.

After the entry into force, member states implemented the Convention with Protocols oriented to adjust structure and functioning mechanism to the constant increasing workload of the court (Egli 2007, p. 7). According to the original design, the court envisaged a double-step mechanism: a commission performed monitoring tasks analyzing claims' conformity to admissibility criteria and attempting friendly solutions, whereas a court performed adjudicatory tasks. The accession to ECHR of new member states after the fall of the Berlin Wall dramatically increased the

number of claims: Protocol 11, entered into force on 1 November 1998, was imagined to deal with the huge number of pending applications. The articulated mechanism moved from a mix of monitoring and adjudicatory tasks to an entire judiciary system, based on a single court working on a permanent basis: the elimination of the commission screening function simplified and made the procedure more concise. Furthermore, it allowed individual applicants to present claims directly to the court.

Despite its purpose, Protocol 11 failed to deal with the ECtHR workload, and a number of applications incessantly increased during years. In 1999, right after the introduction of Protocol 11, the number of pending applications was 12,600; 10 years later, pending applications amounted to 119,300 (ECtHR statistics 2013, p. 7). Member states issued Protocol 14, which entered into force on 1 June 2010 and provided further reforms aiming to grant long-term efficiency and strengthening applications' process. The protocol reduced the decision body formation for the simplest claims, conditioned the admissibility of claims to further admissibility criteria requiring "a significant disadvantage" for the applicants, and prolonged the judges' term of office from 6 years with option of reelection to nonrenewable 9 years term providing for expiration of the office when they reach 70 years of age.

Currently, members have adopted Protocol 15 introducing references to the principle of subsidiarity and the doctrine of the margin of appreciation and reducing from 6 to 4 months after the date of the final domestic decision the time limit within which the claims should be filed and Protocol 16 allowing the court to give advisory opinions on questions of principle related to interpretation and application of rights, upon request of the highest domestic courts. Both protocols will enter into force only once contracting states will sign and ratify them.

Organization

Issuing durable legal rules per se does not make a regional human rights system effective, if there is

no assignment to third parties of the task of interpreting and applying rules. ECtHR carries out exactly this role and makes the international regional system established by ECHR capable of enforcement. The effects of the incorporation of ECHR together with the functioning of the court as a constitutional court and the effects of ECtHR judgements allow denial of those theories that support a qualitative difference between international regimes and states; thus doubting some form of constitutionalism beyond states is feasible (Rosenfeld 2010). Recent theories argue that the ECHR framework evolves into a transnational constitutional regime (Stone Sweet 2012).

The ECtHR has its headquarters in Strasbourg and is composed by elected judges, chosen either among judges eligible for high judicial office or jurists of esteemed competencies. The number of judges is the same as the number of the high contracting parties (47 at present). The Parliamentary Assembly elects judges with majority of votes, among a shortlist of three candidates presented by each contracting party.

Judges must have high morality: although representing one state, they hear the claims in their individual capacity. Thus, they must avoid any activity which endangers their impartiality and independence.

Depending on the complexity of the case, the ECtHR scrutinizes the claim sitting in one of its four judicial formations. When inadmissibility of the claim clearly appears without any further investigation, the single judge has the power to strike the complaint out of the list of the cases or declares its inadmissibility with final decision. When this is not the case, the single judge forwards the claim either to a Committee or to a Chamber. The Committee unanimously decides either to declare inadmissible the claim or strike it out when no further investigation is required or to declare it admissible and simultaneously issue the judgement on the merit when the question is the object of well-established jurisprudence. Alternatively, the Chamber rules on the merit of the claim, together with a decision on admissibility or separately. In the exceptional situation in which the case concerns a question seriously affecting ECHR interpretation or which might

lead to a decision contrasting with a previous judgements, the Chamber relinquishes jurisdiction in favor of the Grand Chamber of 17 judges. Moreover, one or both parties might require referral to the Grand Chamber within a period of 3 months from Chamber judgement's delivery.

Procedural Issue

ECtHR has jurisdiction to hear claims filed by individuals or state and alleging that one of the high contracting parties violated the ECHR. Jurisdiction includes all the matters related to interpretation and application of the ECHR; however, the court shall not take case on its own motion. Since the introductory phase, the procedure stands out for its accessibility and effectiveness. Both states and individuals, either person, group of people, or non-governmental organizations, have the right to present claims, thus granting widest access to justice.

A complaint undergoes two steps, with some faint adjustments concerning the analysis depending on the judiciary formation scrutinizing it. The first is the admissibility stage during which judges verify the observance of some formal requirements.

Claims must concern one of the rights covered by ECHR, not to be manifestly ill-founded and be direct against one or more states parties of the Convention. Following a general rule of International Customary Law, applicants shall exhaust all the available domestic remedies, up to the highest level of jurisdiction, and resort the ECtHR within 6 months following the date of the last judicial decision. Last, the applicants shall have suffered a significant disadvantage: the violation, although real from a mere legal point, shall overtake a minimum threshold to deserve international judges' attention. These requirements reflect different purposes: the former grants national authorities the opportunity to prevent, or at least to fix, violations, whereas the latter facilitates the activity of the court making it easier when dealing with unmeritorious claims and allowing devotion of more time to serious claims. Both rest on the same assumption: the subsidiarity of ECtHR

with respect to national mechanism of safeguarding human rights. Thus, on one side, national courts have at first instance the chance to deal with questions regarding the compatibility of domestic law with the Convention. On the other side, the court stands as a supranational court of final instance deserving the analysis of substantial claims and denies the role of an alternative channel to which require further monetary damages.

Past the admissibility screening, judges scrutinize the merit of the claim and undertake further investigation, if needed, inviting parties to submit further evidence and written observations or fixing public hearings with the representatives of the parties. At the end of the investigation, judges deliberate on the question and issue a judgement, providing reasons for the decision, which becomes final if parties declare to renounce or do not request referral to the Grand Chamber within 3 months.

In principle, the final judgement is declaratory in nature (*Marckx v. Belgium*, appl. number 6833/74 1979 par. 58). Only in 2011, the court introduced an original mechanism aiming at optimizing time and resources allocation when dealing with cascade of repetitive claims, which does not necessarily end with a declaration that a violation has been committed. When applications underline the existence of a structural or systemic problem, the court might issue a pilot judgement after processing them as a matter of priority. The pilot judgement contains both the identification of the nature of the structural problem or the dysfunction and the suitable remedies the defendant state is required to adopt.

Final judgements are binding upon the parties of the cases. The declaratory character implies that the court renounces to impose on the breaching state any obligation to adopt specific measures necessary to ensure compliance, a part for some exceptional cases. The execution of the final judgement consists into the performance of two groups of obligations, depending on the measures required. The first one demands adoption of general measures and includes the obligation to execute the violated provisions and to prevent the occurrence of further violations. The second one consists into the obligation to put an end to the

violation and fix the negative effect, the execution of which required individual measures.

General measures aim to prevent future violations similar to the ones found by the court and most of the time require changes in legislation. However, when national authorities recognize direct effect to judgements, publication and dissemination of the decision is sometimes enough to induce national effective remedies.

Individual measures aim to put an end to the violation and to *restore as far as possible the situation existing before the breach* (Brumarescu v. Romania 1999, par. 19). Thus, following customary rules of international law, *restitutio in integrum*, aiming to take the injured back as far as possible in the same situation as the one he enjoyed before the violation, represents the preferred relief. When the restoration of the injured victim is otherwise impossible or only partial, the court might award monetary compensation.

The Committee of Ministers is the organ charged of supervising the execution of the judgements. The Committee organizes two meetings a year and gathers one representative for each contracting party (in principle the Minister of Foreign Affairs), each of whom is entitled to one vote. The monitoring function of the organ includes the supervision of the execution of friendly settlement and judgements (White and Ovey 2010, p. 53). The Committee invites the respondent state to explain the measure taken to avoid the consequence of violation and provide evidence of compensation payment: the Committee supervises regularly each case until it is satisfied with the adoption of general measures necessary to ensure compliance.

Just Satisfaction

Besides the general freedom in the execution of the judgements, the ECHR provides the court with the power to award compensation for injuries suffered, as a residual remedy for those damages that cannot otherwise be repaired. The core of the system lies in article 41 that provides for just

satisfaction. The provision envisages that if a violation is found and *if the internal law of the contracting party concerned allows only partial reparation to be made, the court shall, if necessary, afford just satisfaction to the injured party*. The court might exercise the power to afford just satisfaction to victims in the same judgement if the question is ready for decision and claimants specifically require monetary compensation. Just satisfaction is a compensation for an actual harm: finding of evidence of violation does not automatically grant a positive award, being a matter of court discretion. The letter of the provision is clear when specifying that the award is not a direct and automatic consequence of the finding of violation. Judges determine to award just satisfaction upon a specific applicants' request supported by appropriate documentary evidence. The approval of the request is conditional on the inadequacy of national remedies to provide full reparation to victims. In addition to subsidiarity, the award shall be necessary and just.

Economic analysis of law acknowledges damages as an instrument having twofold function: restoring the injured for the harm suffered (compensation) and providing injurers with behavioral incentives fostering internalization of the externalities (deterrence). Due to their economic function, in general, damages shall provide full compensation for the victims' losses because only in this case the injurer internalizes the negative externalities produced (Posner 2003, p. 192). Nevertheless, compensation of damages within the international public field assumes a peculiar meaning considering that the court exercises only a weak form of review (Bernhardt 1994, p. 297), but aims to provide "constitutional justice," rather than "individual justice." On one side, when finding a violation of the Convention, judges' declaration of incompatibility with ECHR does not replace the questioned law with one of its own making, nor directly affect the validity of that law in the national legal system. On the other side, the actual function of the court is to ensure that administrative and judicial processes in member states effectively conform to pan-European convention standards, rather than seeking to provide every deserving applicant

with a remedy for the Convention violation (Greer 2003, p. 405).

Traditional economic theories argue that damages do not have to fully compensate harm, as long as they make taking due care the most attractive strategy (Visser 2009, p. 155). However, having regard to the international human rights protection framework, under-compensation of the harm caused might not be sufficient in view of obtaining the ultimate goal of the court, namely, the adoption of a standard of protection appropriate to the ECHR. On the other side, the rules specifically clarify that the court does not aim to punish the breaching state for its responsibility in violating the Convention and invite to charge as inadequate any claims for *punitive, aggravated or exemplary* damages. Just satisfaction turns out to be the result of a balance between the interest of injured applicants to receive some sort of satisfaction and the public interest of defendant states, with an eye to the local economic circumstances of the state.

The award, if any, is exclusively in the form of a sum of money to be paid by the respondent state within a time limit that usually the court sets in 3 months. Judges might either award a global sum, either breakdown just satisfaction into three components that correspond to material losses, moral losses, and costs and expenses. Practical indications on the computation of material damages refer to the principles of International Customary Law codified by the United Nations Law Commission (chapter IV.E.1, article 28 and following). The basic principle rests upon the assumption that the injured applicant *should be placed, as far as possible, in the position in which he or she would have been had the violation found not taken place*. Material damages awards concern economic losses and would in principle reflect *the full calculated amount of damages* or a reasonable estimation based on observable facts.

Moral damages include a mixture of highly intertwined elements, many of which involved social and psychological aspects: it is a matter of civil law jurisdiction, rather than an instrument of public international law (Parish et al. 2011, p. 225). This concept recurs in context of tort

that causes intangible, or otherwise difficult to quantify, injuries to a person and/or his/her rights, including pain and suffering, anguish and distress, and loss of opportunities. Assessment of moral damages is difficult because moral losses are not directly visible (Shavell 2004, p. 242; Aarlen 2013, p. 439). The court itself admits that *it is in the nature of nonpecuniary damages that it does not lend itself to precise calculation* (Practice Directions, section III, par. 13). As a matter of fact, assessment of damages grounds on equitable arguments and standards emerged by case law.

Empirical Studies Focusing on ECtHR

ECtHR counts the biggest caseload among international courts, with more than 17.000 judgments delivered since its creation, and makes most of the information about the cases publicly available. This makes the court as a suitable object of attention when investigating the more relevant issues related to effectiveness of international adjudication.

Voeten (2008) investigates international judicial behavior, focuses on impartiality of ECtHR judges, and considers the court as a committee of individual judges, rather than a single actor. Focusing on the minority opinions expressed by judges, he evaluates what determinants other than law, if any, systematically affect judges. Findings show that ECtHR judges' behavior is more similar to that of national review courts, rather than political institutions: there is no evidence that judges' domestic legal culture is a matter of concern, and the overall effects of career motivation are moderate (despite some evidence that judges show national bias in evaluating politically sensitive case). The study is overall positive toward the possibility of impartial review and suggests ECtHR judges are politically motivated actors having political preferences on to the best way to apply abstract human rights, but they do not use their power to settle geopolitical scores.

Helfer and Voeten (2014) take the ECtHR rulings on a specific issue, namely, lesbian, gay,

bisexual, and transgender rights, to investigate the effectiveness of international tribunals as agent of policy changes. The study aims to investigate whether the court affects the behavior of actors other than parties to a dispute or, contrary, the court simply reflects evolving social trends and adapts its jurisprudence to the evolution of national policies. The study contributes with an empirical assessment to the path of literature trying to provide analytical explanation of the effectiveness of international adjudication activities (Helfer 2014). In particular, it focuses on what has been classified as the *erga omnes* effectiveness and *norm development effectiveness*. Findings show that international law created by ECtHR jurisprudence systematically affects domestic judicial review and legal changes. ECtHR judgements increase the likelihood that all COE members, even those that are not found to violate the Convention, adopt friendly LGBT rights reforms, and the effect is much more evident where support for LGBT rights is relatively low. Based on statistical findings, the authors argue that the ECtHR court contributes to legitimize and justify political changes especially with respect to lazy countries. The court engages in majoritarian activism, rather than aggressive policy, and reverses previous decision only when at least a majority of COE members have already done so.

European Integration

Aurelien Portuese

University of Westminster, London, UK

Abstract

European integration is a process. It is a process of institutionalization by which the old continent is continuously transformed either through incremental changes or through across-the-board reforms. European integration designates the changing current institutional framework of the European Union (hereafter EU). The European continent

experiences other institutional integration than the EU's – mostly the European Convention on Human Rights – but the focus shall be put on the EU as this regional organization is the most significant and integrated one.

The history of the European integration has paved the way for an entire new legal order with a strong economic rationale to come to the fore (I). The emphasis of institution-building and market-building has nevertheless not been without difficulties in terms of construing a common political structure, democratically legitimate for the European national democracies (II).

Definition

European integration is an expression describing a process, by opposition to a state of affairs that would be mainly unchanged. Hence, the European integration defines an institutional process taking place within a regional organization by opposition to an institutional state of affairs created suddenly through different forms of state such as a federation, a regional state, a nation-state, etc.

The EU is not a state; it is an organization so much of its own that it is commonly described as being a *sui generis* organization. The EU should not be looked at or investigated as photography but rather as a movie in the making – hence the expression “European *integration*.”

The history of the European integration has paved the way for an entire new legal order with a strong economic rationale to come to the fore (I). The emphasis of institution-building and market-building has nevertheless not been without difficulties in terms of construing a common political structure, democratically legitimate for the European national democracies (II).

The Law and Economics of European Integration

The history of the European integration portrays a strong economic underpinning of the common

destiny the European states have decided to embrace (a). Out of the economic system set up in the aftermath of the Second World War, an ongoing process of institutionalization has continuously transformed the European integration to become nowadays the most institutionalized region of the world. This process has spawned a new legal order – the European Union (EU) law – which is imbued with economic considerations (b). The European institutional framework and practice that result from this evolution is, from a law and economics perspective, driven by an economic efficiency rationale (c).

Economics of European Integration: Peace and Prosperity Through Reciprocal Stakes

On a continent repeatedly ravaged by wars and erstwhile enmities, and on a continent continuously disheartened by peace treaties violated, new peace-making solutions have appeared to become imperative during the postwar period. Diplomatic relations had not been so far satisfactory: only economic interdependence would make peace durable.

Because peace leads to prosperity, the argument of this Kantian perspective is circular: an economic integration paves the way for an ever-greater economic interdependence among European states allowing for peace and prosperity on the continent (Kant 1992).

The interlinkage between commercial knots and peace-building is well known since Montesquieu wrote: “The natural effect of commerce is to bring peace. Two nations that negotiate between themselves become reciprocally dependent, if one has an interest in buying and the other in selling. And all unions are based on mutual needs” (Montesquieu 1758, p. XX).

Therefore, the architects of the European integration were driven by fostering the self-interest of each state to make peace: the challenge was not so much about having a possible peace treaty to be signed but more about having war made impossible. Indeed, the economic interdependence created by free trade would render war impossible among rational and self-interested states.

The birth of European integration has consequently been triggered not by setting up

a “superstate,” a federation, or any other grand projects against which nation-states were reluctant to build. It has been driven by rational choice perspective and by the progressive deconstruction of the protectionist powers of the state.

Without coincidence, the first sectors of the economy to be integrated into a common pool were the coal and steel of European nations since coal and steel were the raw material for wars. The Schuman Declaration of 1950 in which Robert Schuman, French Minister of Foreign Affairs, called for a “step-by-step” process of integration leading to a European federation. This declaration heralded the creation in 1951 of the European Coal and Steel Community (ECSC), with a High Authority managing the production and the distribution of coal and steel in Europe. Consequently, with the ECSC, war has been rendered materially impossible (Pelkmans 2006).

In light of the success of the ECSC, the founding members – France, Germany, Italy, Belgium, Luxembourg, and the Netherlands – generalized this success to all sectors of the economy by creating a free trade area through the abolition of customs duties and the proclamation of the free movement of workers, capital, goods, and services. This was the creation of the European Economic Community (EEC) in Rome in 1957 (Duchene 1994).

The common market laid down by the EEC was constituted of a customs union made of free trade area (abolition of tariffs within Member States) and a common external tariff with respect to non-Member States. Also, the four economic freedoms (free movement of goods, services, workers, and capital) were proclaimed. Finally, few common policies were envisaged, such as the Common Agricultural Policy.

There are four stages of economic integration: a free trade area, a customs union, a common market, and finally an economic and monetary union. Before embracing a monetary union with the creation of the Euro in 1992 with the Maastricht Treaty, the EU has therefore jumped from its inception in 1957 into a very integrated regional union – a common market with a common external tariff and with common policies.

A 12-year transition period was granted in order for Member States to abolish their custom tariffs. In 1969, the common market was accomplished. The removal of barriers to trade and the large-scale competition allowed for over the entire continent would stimulate modernization of the economies by the lowering transaction costs, the enjoyment of economies of scale, and the enhancement economic efficiency. The belief in the net positive effects of a customs union was widely shared among economists.

The most influential theory at that time was Jacob Viner's theory of trade creation and trade diversion. He argued that economic integration leads to two simultaneous welfare effects: trade creation among Member States and trade diversion among Member States. Whether trade creation (welfare-enhancing effects) is greater than trade diversion (welfare-decreasing effects) depends on the structure of the economies to be integrated. The relative similarity of the European economies in 1957 led economists to vouch for economic integration through a common market given its plausible net positive effects in terms of trade creation (Pelkmans 2006).

The common market created by the EEC was the means to achieve an everlasting peace and prosperity on the continent. The common market has been a success in its realization. Indeed, from 1958 to 1972, while trade between the six founding Member States and the rest of the world had tripled, intra-community trade had been multiplied by 9 (Pelkmans 2006).

If the European integration had strong economic rationale due to the creation of a common market to the six founding Member States, the European common market could not last without a sufficient degree of institutionalization and a European law that encapsulate this economic rationale.

Law of European Integration: Institutions as Engines of Economic Integration

The effective working of the European integration requires a delegation of authority, even sovereignty, to supranational institutions. This requirement is derived both from the high reluctance of Member States to rely exclusively on other

Member States for the implementation of the rules creating the common market and from the economic rationale of such institutions since decision-making costs are reduced, thanks to the specialization of supranational institutions.

The European Institutions

The institutions of the EEC are representatives of different interests. While intergovernmental institutions within which Member States play a key role represent national interests, supranational institutions within which European institutional actors are predominant represent the "community" interest.

The intergovernmental institutions of the EU are the Council of the European Union and the European Council. The supranational institutions of the EU are the European Parliament and the European Court of Justice.

The European Commission is the similar to a cabinet government, composed of 28 members of the Commission ("commissioners") – one per Member State – who execute the European Treaties. It represents the general interest of the EU. The President of the European Commission is proposed by the European Council and elected by the European Parliament.

The European Parliament is the directly elected legislative assembly of the EU since 1989 where European citizens are represented. Composed of 766 members, the European Parliament has incrementally gained legislative powers to achieve equal footing with the Council of the European Union under the ordinary legislative procedure generalized since the Maastricht Treaty of 1992. Under the ordinary legislative procedure provided at Article 294 of the Treaty on the Functioning of the European Union ("Lisbon Treaty" of 2009), the European Commission has the monopoly of legislative proposal. The European Parliament adopts a first position; if this position is approved by the Council, the piece of legislation is adopted. If the Council disapproves the Parliament's position, it adopts its own position and then communicates to the Parliament who either approves or disapproves the Council's position. In the latter case, a so-called conciliation committee is convened, composed of an equal number of Council's

members and of Parliament's members. If the conciliation committee adopts a joint text later approved by both the Council and the Parliament, the legislative act is finally adopted. If the conciliation committee fails to adopt a joint text, or adopts a joint text but not later approved, the legislative act is not adopted.

The European Court of Justice is designed to be the supreme court of the European Union by ensuring full compliance with European law by the Member States and European citizens. Seated in Luxembourg, the European Court of Justice is composed of independent judges from different Member States representing the different legal traditions present in Europe. Helped by the General Court and the Tribunal for Civil Servants, the European Court of Justice can hear cases either directly or from national tribunals (Turk 2010).

The Council of the European Union composed of national ministers represents the Member States with each Member States being allocated different voting weights according to its political power.

The European Council, originally in 1974 an informal of the head of states and governments of the Member States, has been recognized as a European institution in 1992. This high-level meeting instills the political impetus to the European Commission and, since the Lisbon Treaty of 2009, is chaired by the President of the European Union. The President is elected by the member of the European Council and its term lasts 2 years and half, renewable once.

This sophisticated institutional framework progressively, through treaty amendments, resembles one of a federation of states despite an added complexity due to the reluctance of Member States to renege upon their sovereignties.

The European institutions have been granted powers independent from Member States only to the extent that the Member States benefited from these delegations of powers in favor of these institutions acting as their agents. Indeed, the European institutions have been tasked with the completion of an internal market within the European Union. In order reach such result, the necessary functions have been delegated to the European institutions – this is the “neo-functionalism” theory as we shall discuss below.

The European Law

The completion of the internal market required European law to materialize the economic objectives of the European integration – namely, a customs union, the four economic freedoms, and a competition policy. European economic integration could only emerge through European legal integration. “Integration through law” has been the major force toward the completion of the internal market, with the European Court of Justice working as the primary engine of integration.

First, the European Court of Justice has elaborated a thought-provoking case law ensuring the greatest effectiveness of European law over national laws (Weiler 1991; Turk 2010). The European judges have granted to European law direct effect, making most of European law directly invokable by litigants before any national and European court. Also, the European judges have trumped national laws by continuously proclaiming the primacy of European law over any national laws (Weiler 1991). Moreover, the responsibility of Member States has been engaged any time European law is not respected in the given Member State by whatever national institution, citizen, or organization of that state. Also, the European Court of Justice reaffirmed its role as the supreme court of Europe by interpreting largely its monopoly of interpretation of European law and of annulling European law in light of the European Treaties (Weiler 1991). Therefore, not only have European judges confirmed the essential role of European law in the national legal orders, but also have they placed themselves as powerful judges in the most influential court in Europe (Bernard 2010).

Second, after having ensured its maximum effectiveness, European law has been developed and interpreted in order to maximize the extent to which the process of building the internal market is conveyed. Ernst Haas, one of the fathers of the functionalism theory, said that “the most inviting index of integration – because it can be verified statistically – is the economic one.”

Market-building requires rules on the prohibition of discrimination since goods, services, capital, and labor must compete within a market on

a fair and open basis. The customs union is efficiency-enhancing on one part because it creates some trade but can also be efficiency-decreasing on the other part because trade can be diverted due to the discriminatory rule a customs union creates in favor of its members and in disfavor of the nonmembers. Hence, the customs duties (Article 30 TFEU) and “measures having an equivalent effect” (Article 34) are prohibited within the EU after the 12-year transitory period. The notion of “measures having an equivalent effect” has been given great scope by EU judges to encompass lots of regulatory measures. Indeed, “all trading rules enacted by Member States which are capable of hindering directly or indirectly, actually or potentially, intra-Community trade are to be considered as measures having equivalent effect to quantitative restrictions” said the EU judges in the famous *Dassonville* case of 1974. Despite the fact that some mandatory requirements can potentially be accepted as justification for some national regulations (see case *Cassis de Dijon* of 1979) above the justifications provided for in the treaties, the *Dassonville* formula has been continuously reaffirmed by the case law (Bernard 2010; Turk 2010).

Therefore, the EU legal order has been designed around the notion of competitive order – in other words, the internal market requires a law that ensures that competitive forces work openly, fairly, and on an equal basis for all market participants. Thus, in order to limit the reduction of economic efficiency and to increase the internal efficiency of the market, two legal dispositions had to be added at the top of the prohibition of customs duties and measures having an equivalent to quantitative restrictions. First, a nondiscrimination rule had to be an overarching principle of market-building. Second, a strong enforcement of a common competition law had to be ensured. The European successfully encapsulate both dispositions so that the internal market could be considered to have been completed by 1992 with the Maastricht Treaty.

First, the prohibition of discrimination on the basis of nationality enshrined in Article 6 of the Treaty of the European Union, in Article 21 of the Charter of Fundamental Rights of 2000 (a sort of

EU “Bill of Rights”), ensures equality in the internal market, hence its smooth working. It is no surprise that the EU judges have interpreted the nondiscrimination principle in a very ambitious manner. The nondiscrimination principle applied very broadly in the field of the free movement of goods is progressively applied in a comprehensive manner to other economic freedoms. Hence, the “market access” has, in the eyes of the EU judges, to be secured in the broadest manner in all fields of the internal market through the resort of the nondiscrimination principle writ large (Bernard 2010). Market access must be ensured due to the benefits of transactional efficiency (in terms of minimization of transaction costs created by national regulations) expected to be reaped out by internal market participants (Portuese 2012, pp. 361–402).

Second, European competition law had preserved the internal market from obstacles to its achievement (the so-called objective of “market access”). The basic EU competition rules are found in the TFEU at Articles 101 and 102, which lay down a prohibition against restrictive agreements (cartels and collusions) and abuse of dominance, respectively. Articles 101 and 102 TFEU apply to practices or behavior that “may affect trade between Member States” (Toth 2008). The concept of “trade between Member States,” defined in Commission Guidelines (No 2004/C 101/07 of 27 April 2004), implies that there must be cross-border economic activity involving at least two Member States – but, when trade between Member States might be affected, a restrictive agreement applied only in a single Member State will not be excluded from the scope of EU competition rules. Also, mergers are controlled according to Regulation 139/2004 of 2004. Finally, state aids are circumscribed in accordance to Article 107 of the TFEU. Entrusted with the task of investigating anticompetitive practices, the European Commission is invited to refer to the for potential cases to be tried. The high enforcement of European competition rules have participated in making the internal market a place where a fair and undistorted competition provides the economies efficiencies of a dynamic economy (Bernard 2010).

Overall, the removal of customs duties and charges having equivalent effect, the respect of the nondiscrimination and equality principle, and the strong enforcement of European competition rules have contributed to materialize European integration over decades. If European integration has been propelled by the European institutional actors such as the European Commission and the ECJ, it is also due to the particular appeal the pursuance of the notion of economic efficiency had on these supranational actors.

European Institutional Actors as Agents of Economic Efficiency: The Efficiency Hypothesis

The foundations of European law are substantiated in the general principles of EU Law. With the principle of equality and nondiscrimination discussed above, there are three main general principles that govern European law – the principle of subsidiarity, the principle of proportionality, and the principle of legal certainty.

The principle of subsidiarity is double-edged. Enshrined in the Treaty of the EU at Article 5 (3), it can be used to justify both increased centralization and increased decentralization. The principle of subsidiarity can justify further centralization because it requires that the most appropriate level of governance be chosen for exercising a particular power. A study of the principle in general, and in practice as interpreted by the EU judges, reveals that the principle of subsidiarity both is a principle of economic governance and is interpreted in an economically efficient way by the EU judges (Portuese 2011).

The principle of proportionality is a general principle of EU law explicitly stated in the EU Treaties nowadays at Article 5 (4). The EU proportionality principle can be divided in different sub-principles: (i) the review of the necessity of the measures to achieve the desired objective, (ii) the review of the suitability (or less-restrictive means test) of the measures for the achievement of the objective, and (iii) the review of the proportionality *stricto sensu*, whereby the burden imposed must be of proportion with the goal desired. If the first sub-principle is tantamount to an effectiveness criterion, the second

sub-principle ensures the efficiency (ratio means-ends) of the measure, while the third sub-principle involves a balancing exercise of interests similar to a cost-benefit analysis which itself fosters Kaldor-Hicks efficiency. Therefore, the overall principle is and is interpreted as an efficiency principle (Portuese 2013).

Finally, the EU principle of legal certainty protects the legitimate expectation of market actors. Therefore, it ensures that changes in the law occur at a predictable path and in a reasonable way. If this guarantee is not respected, then damages must be awarded in order to compensate the loss of market actors' proprietary interests. This principle has been jurisprudentially created in the EU, so the European integration can happen without loss of proprietary interests, thus without disincentivized internal market actors (Portuese 2014a, b).

Along the general rules of European integration such as free movement rules and competitions rules, the general principles of EU law are efficiency-enhancing rules and have been interpreted as such consistently by the EU judges.

There is no coincidence however.

Indeed, one must recall the high distrust Member States had one another in the aftermath of the Second World War. Therefore, a relatively strong supranational institutionalization has been erected in order to eschew reciprocal and the tit-for-tat ill-fated strategies of classical treaties. Consequently, any political answers favoring one specific Member State or a given group of Member States at the expense of other Member States had to be seriously sidestepped. Indeed, welfare distribution would have been seen at that time as a means for a Member State to get a hold on the overall European integration. Thus, the European construction was only left, politically speaking, with a solution of welfare creation: an economic solution secured by the law (Portuese 2012).

In that prospect, economic efficiency is a rather neutral notion, despite its criticisms. It does not favor a specific Member State over another; it promotes the general interest of Europe inasmuch as supranational institutions were tasked to promote. Hence, supranational institutions of the EU have been keen to develop the economic

efficiency within the internal market because it is both an engine of integration and, very notably and interestingly for them, a politically accepted objective.

In light of the cursory economic analysis of European law discussed above, it can be said that there is tendency of European law in general and of European case law in particular to develop in sense that promotes economic efficiency. Therefore, a hypothesis of the economic efficiency of the European case law can be made, by reference to the classical and contested economic efficiency hypothesis of the common law (Portuese 2012).

If European integration has been in great majority about economic integration, the creation of a supranational polity having manifest powers over the economic environments of Member States but without possessing the democratic legitimacy of national democracies raises the everlasting concerns of European integration.

The Law and Politics of European Integration

If European integration has been for long driven by economic grounds unfolded by the ECJ case law (Turk 2010), the political integration was more diffident since Member States were both reluctant to share the prestige of their national legitimacies and to set up, from the onset or later at the end of twentieth century, a European polity capable of being compared to any form of federation or superstate (Weiler 2000). This reluctance can be understandable but is nevertheless problematic for at least two reasons: the very essence of European law becomes under fire given the low legitimacy of this “undemocratic” law (a), and the very essence of the European institutions also evolves into an easy target for criticisms due to the lack of the commonly recognizable features of national institutions shared by the European institutions (b).

In fact, the European Union is based on an inverted construction where market-building has preceded and primed over institutions building. The European Union, a *sui generis* organization,

can be defined by the concept I introduce of *soft federation* (c).

Harmonizing Details and Enlarging High-Tail: Challenges to the Law

The European construction has developed European law to an extent that it becomes difficult to find sectors of the economy where regulations have not been harmonized at the European law. Indeed, the EU works predominantly as a regulator, privileging the normative power over military power.

The EU can only regulate, however, when it is directly related with the internal market. This is in accordance with the principle of conferral of powers.

When sectors are not harmonized, the so-called principle of mutual recognition applies: it means that the national rules have to be mutually recognized by the other Member States (Armstrong 2003). Hence, traders do not have to comply with extra rules that are purported to achieve objectives for which the rule of their home country has already been designed to achieve. Extra national regulatory costs are avoided unless mandatory requirements justify compliance with the host state rule. This process is often called “negative harmonization.”

Therefore, as an incentive, the European institutions have been keen to harmonize at great pace. The removal of all barriers to trade can sometimes lead to the hastened removal of national rules. Therefore, harmonization with one single European rule is needed in order to foster the integration of the internal market. This process is often called “positive harmonization”.

Negative harmonization is deregulatory; positive harmonization is re-regulatory.

The interesting point to raise in the following lines is not about how much, what, and when have we harmonized regulations in Europe. It is more about what consequences this process of continuous harmonization bears as challenge to the law as we understand it.

Coupled with the great pace of harmonization is the issue of enlargement (Weiler 2003). Not only have we integrated through harmonization with European rules throughout the European

construction, but also we have enlarged the EU from 6 founding Member States with 169 million inhabitants to 28 Member States with 500 million inhabitants, and it keeps enlarging!

These two major trends of European integration beg the question whether or not European law has enough democratic legitimacy in order to keep both harmonizing in its depth and enlarging in its ambit.

European regulations have recently been under greater scrutiny as for their costs and legitimacy, with the so-called Regulatory Impact Assessment ("RIA") that intends to balance the costs and benefits of each regulation. This tool has been developed under the framework of the "Better Regulation" program – the EU has to be a better regulator rather than a merely effective regulator. But the ambition of better regulating the EU leads to the very notion of legislative acceptability of EU law by citizens with respect to as EU law is perceived.

The law is traditionally understood as being a body of normative rules coherently forming a legal order and applied to a specific territory where subjects are legally binding themselves to this order with full consent. In other words, should the subjects change their mind in a democratically erected legal order, the institutions will be responsive and change the law. Here is the necessity of not binding one generation with another. That's why we have this expression "King in his Parliament": the rules in force are only those expressly or implicitly consented by the people to comply with.

But, as EU institutions can increasingly powers of economic and social regulations, the possibility for national democratically elected representatives to change the law applicable to their citizens. This argument does not work only for deregulating purposes: the mere changes in law are extremely difficult due to the decision-making process taking place at European level that leaves national representatives unpowered.

The notion of EU legal order faces multiple challenges not only for competing with national legal orders that bear high democratic legitimacy but also for ascertaining a minimum prestige owed by European citizens to their European legal order. This prestige is not superfluous, it is

fundamental: a law without prestige is no law inasmuch as a law without sanction is no law. European law with little prestige hardly is law.

National Democracies and Supranational Governance: Challenges to the *Politeia*

If European law faces great challenges in terms of its acceptance and position with respect to the perception of national legal orders, it is also because European integration, again, has been predominantly about economic integration.

The failure of planning, the inability to foresee, the absence of courage, and the reluctance to go supranational have impeded the necessary process of polity-building required by any market-building process. Indeed, the *Politeia* (the Greek word for "polity") defines a specific form of government into which citizens can believe be part of. It does not necessarily mean "democratic" as contemporary understanding evoke; neither does it evolves the notion of Republic nor of nation-state. It only refers to the requirement of having clear and intelligible institutions that citizens recognize as legitimate. Unfortunately, despite efforts made by the Member States and the European institutions to "democratize" the EU by building a supranational polity, the EU institutions are still perceived as far from European citizens. Indeed, the organization since 1979 of direct elections for the European Parliament has not helped this core institution to get credit or to avoid lots of abstentions among voters who are European citizens. Also, the recent creation, with the Lisbon Treaty, of the President of Europe elected by the European Council has not helped European citizens to identify Herman Van Rompuy, the first European President, nor did it helped European citizens to feel he is their European representative (Weiler 2000).

Lots of academic debates are of little help when it comes to increasing the democratic legitimacy of European institutions and to focusing more on polity-building rather than on market-building. One trend of the literature, new functionalism, has argued that the step-by-step integration would "spill over" continuously so that, eventually, an integrated and federated Europe would come to the fore. Within that process, the rise of

a political Europe would emerge as economic integration cannot last without institutional integration (Haas 2004; Sandholtz and Stone-Sweet 1998; Stone Sweet and Fligstein 2001). This process is triggered principally by supranational institutions who act with great independence from Member States. Another trend of literature, labeled “liberal intergovernmentalism,” argues contrariwise that Member States have retained, throughout the European construction, considerable latitude over the European institutions’ powers (Moravcsik 1993). The dynamics of European integration has been, according to that perspective, aligned with the powerful Member States’ interests who succeeded in deepening European integration while preserving their powers.

Beyond this academic debate lays the discussion on a polity-building at the European level which could, if achieved successfully, deliver to the market-building process an enhanced democratic legitimacy. The failure to envision such polity-building or the reluctance to achieve it can be explained by the very nature of the EU. The EU actually is, as I coin, a “soft federation.”

The Political Economy of the Current European Integration: The Soft Federation Hypothesis

In law, soft law is a well-known expression used to designate some quasi-normative rules that are neither hard law because they lack the enforceability of legal rules nor no law because they carry some normative guidelines of certain legal valence.

This concept of soft law can be extrapolated to political sciences and defines a federation that is both insufficiently powerful to be designated as a “hard federation” and insufficiently powerless to be designated as a confederation.

The establishment of a federation generally comes with both the exclusive recognizance of the federal state as depository of sovereignty (both internally and externally), with the creation of police and military powers, the exclusive power over monetary powers, and a preeminence over budgetary powers, and the exclusive power to carry out diplomatic activities. Contrariwise, the federation can intervene less often and deeply on

economic and social matters, the setting up of normative standards, and the policy interventions in fields such as education and research, environmental protection, health policy, etc. But on the other hand, the EU can no longer be considered as a confederation since majority voting has been generalized, whereas confederation are defined by unanimity voting in order to respect each Member State’s sovereignty.

Therefore, an inverse institutional architecture appears compared to classic federation framework: the most integrated parts within the EU are the least one in a federation, while the least integrated parts of the EU are at the essence of the federal level. Therefore, the EU is a federation without the common powers of a federation – it is a “soft federation.”

This hybrid situation is not a middle-ground situation: it may very well last for long, and hence, the “soft federation” format may become a new form of government rather than a temporary one if the “soft federation” hypothesis is confirmed over time.

Conclusion

European integration has been a great success in terms of enhancing the economic efficiency through the process of market-building, while it has remained a great disillusionment in terms of enhancing democratic legitimacy through the process of polity-building.

The two major trends identified in European integration lead to formulate a dual hypothesis: an efficiency hypothesis whereby supranational actors push for internal market rules to promote economic efficiency and a “soft federation” hypothesis whereby Member States push for the emergence of a peculiar federation which protect the core of national sovereignties.

Overall, European integration is a unique process successful enough to witness trials of replications throughout the world (e.g., African Union, Union of South American Nations, Arab League, etc.). This is certainly the strongest proxy for evaluating the results of 60 years of European integration.

European Nationality

Paul-Ludwig Weinacht
Güntersleben, Germany
Würzburg University, Würzburg, Germany

Synonyms

EU citizenship; European identity;
Europeanization

Definition

European Nationality (EN) is a concept with two meanings: the present legal, political, and cultural reality of the EU (“actual real concept”) and the possible futures of the EU (“target oriented concept”). Both sides of the concept, the “actual real” and “target oriented” ones, are employed in the ongoing process of enlargement and consolidation processes of the 28 (27) EU member states.

An Actual Concept

As an *actual concept* of our legal reality, EN means the EU-citizenship which since 1991 is tied to the primary national citizenship of an EU member state as a secondary one. In the treaty of Maastricht, all citizens of EU member states received the status of general and equal EU-citizenship (Art 17 sq EC). It does not replace the national citizenship, who’s lending or withdrawal remains in the sovereignty of member states – however it complements it in several aspects. The EU-citizenship offers firstly the freedom to settle down and to establish oneself in all member states (Art. 18 EC); secondly it gives the

right to vote in local elections of the state in which someone is legally settled and the right to vote for the European Parliament (Art. 19 EC). Thirdly, the right of diplomatic and consular protection (Art. 21 EC), the right of petition, the right to turn in writing to the organs of the community, p. e. to the representative of the citizens, and to get an answer in the chosen language (Art. 21 EC).

The program by the EP “Europe for the citizens” (2007–2013) intends “to integrate the citizens better in the process of the European unification”; it promotes “the co-operation between the citizens and their organisations from different nations.” The Single European Market is the most integrated institution in Europe. Here the famous “four freedoms” are granted since 1987: free traffic of persons, of services, of goods, of capital. These freedoms are limiting more and more the sovereign action of member states. They act – if necessary by the European Court – as engines for the strengthening of the political system of the EU.

Concerning the political and sociocultural meaning of EN, the EU-citizenship with its rights in annex is largely pre-determined by national preconditions. Conflicts in the context with the banks crisis and in the Brexit-movement in Great Britain showed it. Until now, European citizens as a whole do not form a nation. They do not fulfil the criteria of a nation: neither in the sense of the German or slave concept of nation (origin, history, language, etc.) nor in the French understanding of the word (support for the constitution of one and un-dividable republic).

The EU-citizens in their respective states have a pragmatic relation to the question of more intensive adherence to their nation or to Europe. The answers measured by the Eurobarometer-Survey are often: adherent to collective identities. This refers to “multiples” collective identities in the EU (Trenz et al. 2003, p 17). The mind of the citizen is influenced by the preparation and implementation of the election to the EP and – independently from the election campaign – intensified by culture programs of the EC (2007–2013). “Integration” and “participation” are headwords for the construction of a

well-united European Community, whose identity is based on commonly accepted values (<http://europa.eu/legislation>).

A Target-Oriented Concept

As a *target-oriented concept*, EN is precarious in so far as it applies to the controversial project of a “sovereign European state.” Pro-European politicians like to symbolize the way to this kind of state by a dynamic concept which embraces different fields: “Europeanization.” If the European citizenship would accept criteria of a sovereign state, it would be superior to the national citizenship. In the face of a sovereign position of the EU, some authors mean that common values could be effective in favor of the enlargement of European politics. A specialist means that strong structures and a dense net of competences in European institutions favor the “European identity and public spheres” (Risse 2010).

Prototypical forms of nation-building could serve as an historical example: the French nation as a “product of the state,” because its origin is a sovereign monarchic rule; the German nation as “the base of the state,” because it was – as a type of “community of cultural origin” (Weinacht 1994) – historically prior to the state (Brubaker 1994). The idea of Europeanization could be discussed too at the historic example of England: The political institutions created the English nation, and the political institutions were legitimated by the national English culture (Schulze 2004). It is questionable, if the insinuated lines of nation and institution building will result in a clear definite idea of state and if such an objective will be generally accepted. It is not without reason that the EU-Commission avoids fixing its institutional targets on a definite idea of state (“finality”) and speaks about “an ever closer union among the peoples of Europe” (Treatise of Maastricht 1992/93).

The “Europe of citizens,” which is intended, grows for the time being beside the nations in the form of cross-border sectors of a civil society, which develop both pro-European

and anti-European tendencies. Supporters of this phenomenon try to see in a European “active society of citizen” a new model (Münch 1999).

Is EN Desirable?

Concerning the desirability of European nationality, the Treaty of Maastricht (1992/93) defines the target of the EU as an “ever closer union among the peoples of Europe.” However some Eastern European (“Visegrad”) States have lost this consensus and tend – like France under de Gaulle (“Europe des patries”) – to a “Europe of nations.” With the referendum from June 2016, Great Britain cancelled the treaty of Maastricht in favor of an independent future for its nations. However, the aftereffects of Brexit are controversial. Britons who feel and wish to be part of the European project will loose with European citizenship the privileges inherent in it (especially “freedom of movement”). Many of them have begun to apply for the citizenship of their host country. The Irish embassy in London received 8017 applications for Irish nationality, compared to only 689 applications in 2015. The reason was not the search for a new identity, but the desire to maintain security of residence and the right to travel and live in the 27 countries that will remain members of the EU after the UK leaves (Stone 2017). Politicians and journalists made proposals in favor of a European associate citizenship “for nationals of a former member state” (Henley 2016; Stone 2016).

A European Citizens’ Initiative (ECI) came out informally known as “Flock Brexit” with a Facebook group titled “EU Citizenship for Europeans: United in Diversity in Spite of jus soli and jus sanguineus.” It demonstrates not only the pure pragmatic character of EU Citizenship but Citizenship without political Membership. Although political rights are demanded sometimes, European citizenship is no more than a title associated with the citizenship of an EU member state.

In legal terms, which are underlying the status of European citizen, EN is an actual concept. Its

actual value remains in transnational civil rights, especially the right of movement and entitlement to the same treatment including welfare rights, as the citizens of the country of residence. Prudent politicians declare that the European Union does not substitute the sovereign nations but gives them forward compatibility. That's why EN would remain for a long period a secondary identity.

The transition from the formal status of EU-citizen to a substantial European nationality, realizing what the concept oriented to targets means, is in a quite distant future.

European Patent System

Bruno van Pottelsberghe de la Potterie
Solvay Brussels School of Economics and Management, Université libre de Bruxelles, Brussels, Belgium

Definition

The European patent system is defined as the policy mechanisms, jurisdictions, and institutions in Europe which allow inventors to acquire and enforce industrial property rights over their inventions.

Introduction

The European patent system is a terminology which is often oversimplified and described through the European Patent Convention (EPC). This is a multilateral treaty signed in October 1973 which essentially consists in creating the European Patent Organisation and in providing a legal system for the granting of European Patents. EPC patents, or so-called “European” Patents, are actually not really European, in the sense that they have to be translated and validated in national patent offices in order to be enforceable in national jurisdictions. The European patent system is more complex than the EPC, as it includes three layers of legal rights (national patents, the current European Patent, and the forthcoming Unitary Patent). Two types of patent offices grant these rights: national patent offices (which grant national patents) and the European Patent Office for the granting process of European and Unitary Patents. Litigations currently take place at the national level, and for unitary patents patent litigations should be treated by a Unified Patent Court, whose design is currently being framed and negotiated, as of January 2015. This entry aims at providing a wide understanding of the European patent system, its strengths, its weaknesses, and its challenges.

Chronology of Three Patent “Layers”

As of the late nineteenth century, all European countries had a national patent office that would grant national *patents*. The broad patentability conditions, found in most patent systems around the world, include novelty and inventiveness. In order to be granted, a patent must be novel (i.e., it should not have been published or made public prior to the application), and it must be inventive (there must be an inventive step, or non-obviousness, with respect to the prior art). If the patent owner aimed at extending its geographical coverage, it had to file subsequent applications in other European countries. This was particularly complex and costly, as it led to

additional translation costs, application fees, and examination fees, not to mention renewal fees to maintain the patent in force once it was granted, for a maximum duration of 20 years from the first date of application. According to the Paris Convention (March 1883), which is still in force today, patent owners have maximum 1 year after their first application to extend their patent abroad while not being refused on the ground of the novelty condition (a patent published elsewhere would constitute a prior art) (Table 1).

A second layer of patent protection was activated in 1978. It is known as the “European Patent” and was set up through the creation of the EPC, signed by 38 countries, as of June 2014 (including all countries of the European Union).

Source: figures on patent applications, granted and in force, are from WIPO statistical series released in 2014. Fees are from de Rassenfosse and van Pottelsberghe (2013) and represent cumulated fees from application to grant, in EUR

In short, once granted by the European Patent Office, a patent must be managed and enforced at the national level. This “European” terminology is therefore often confusing, and certainly inadequate, as the “European” dimension only takes place for the processing of the search report and the substantive examination of patent applications. They are centrally granted by the European Patent Office. Once granted these patents must still be validated and renewed in the national patent offices that fit with the desired market coverage of the patent owner. The cost of a European Patent is therefore relatively high and depends on its geographical coverage, as inventors must pay their validation fees and several other costs (intermediates, patent attorneys, renewal fees). An opposition procedure before the EPO can be initiated by any person or institution during a period of 9 months after the date of decision to grant a patent. Any subsequent litigation is operated at the national level (see Guellec and van Pottelsberghe 2007 for a broad introduction to the economics of the European patent system).

Table 1 presents these first two “layers” of patent protection. National patent offices receive national patent applications (ranging from a few hundreds in small countries to more than 60,000 in Germany and 23,000 in the UK). The cumulated number of patent applications at national patent offices (about 132,000) is smaller than the 150,000 patent applications filed at the EPO. Interestingly, the EPO is particularly targeted by foreign companies, as 51% of its patent applications are filed by non-EU residents. National patent offices are less targeted by foreign companies (only 21% of patent applications are filed by nonresidents).

Countries inside Europe have adopted different fee structures and policies. The last column of Table 1 shows that the cumulated fees from application to grant fluctuate from less than 300 EUR in the UK or the Netherlands to more than 1,000 EUR in Italy, Finland, and Denmark. When it comes to the European Patent, the fees for patent prosecution before the EPO are much higher than in national patent offices, with more than 4,000 EUR of cumulated fees, from application to grant. And these cumulated costs do not reflect the

maintenance rates of European Patents in each national jurisdiction.

The fragmentation of the European market is ultimately illustrated by the very strong heterogeneity in the number of patent in force across countries. Germany, France, and the UK have by far the largest number of patents in force, more than 450,000 (be they granted by the EPO or by their national patent offices). All other EU countries have much less than 100,000 patents in force, due to their smaller size and hence lower market attractiveness. It is worth noticing that a European Patent becomes particularly expensive once it is granted, due to the translation costs and cumulated renewal fees. This is well illustrated in Fig. 1, which shows the evolution of cumulated costs for patents that aim at being put in force in 6 or in 13 European countries, as compared with Chinese, Japanese, South Korean, or US patents.

The main consequences of the system that combines national and “European” Patents are described in Mejer and van Pottelsberghe (2012) and in van Pottelsberghe (2010). The most visible one is related to the prohibitive costs of patent protection in Europe, as compared to several other regions in the world. A European Patent with protection secured for 10 years in 13 countries will cost more than 30,000 EUR, against less than 5,000 in the USA, Canada, China, Brazil, Japan, or South Korea.

Another important consequence of such fragmentation is related to the broad legal uncertainty associated with the European Patent, especially for technology-based spin-offs. Legal uncertainty is the outcome of a dual system in which the EPO grants patents centrally but where national patent systems have the ultimate power to validate, invalidate, and assess infringement proceedings relevant to their own jurisdiction. European Patents which are particularly valuable have a high propensity to be litigated, in several countries. Parallel litigations are extremely expensive and time-consuming, especially for small entities. Then come the incongruities, whereby a patent can be maintained valid in one jurisdiction and invalidated in another. And even if a patent is maintained valid in several jurisdictions, they

European Patent System, Fig. 1 Ten-year cumulated patent fees for a European Patent (validated in 6 and 13 countries), compared with the US and three Asian countries (Data source: Mejer and van Pottelsberghe

(2011); cumulated costs (in Euro) from application to grant and renewal in 6 or 13 EU countries (for the EPO) and in the USPTO (USA), KIPO (South Korea), JPO (Japan), and SIPO (China))

may reach opposite conclusions regarding infringement proceedings. Parallel imports are also relatively easy, as infringing products might enter Europe through a country with no patent being enforced and then easily being distributed over Europe. An additional source of inconsistency deserves attention: the fact that national patent offices may grant a national patent even if it has not been applied for at the EPO or if it has been refused by the EPO. Procedurally, it is perfectly permissible to make simultaneous filings at one or several national patent offices and at the EPO. In other words, the granting process orchestrated by the EPO can be “bypassed” if one or more applications are made directly to national patent offices. This practice may have a number of explanations, some innocent (the applicant being interested by only one or two national markets), some less so (a perception that some national offices are a “soft touch” for applications compared with the EPO, and hence applications in the gray zone regarding their patentability can

legitimately be filed at the central and national levels).

These prohibitive costs and legal uncertainty are the main reasons which have prompted policy-makers, for more than 50 years, to try to create a truly European Patent, first called “Community” patent and later entitled “Unitary” Patent, a patent that would bring protection over the whole European Union. This *third layer* has been voted in 2013 at the EU Competitiveness Council at the Ministerial level (Regulation EU No. 1257/2012 for the introduction of the European Patent with unitary effect or the Unitary Patent and Regulation EU No. 1260/2012 for the translation arrangements for the Unitary Patent) and ratified by 25 countries (Croatia, Italy, and Spain did not sign the treaty). The regulations have been adopted by way of enhanced cooperation – a tool that allows a group of EU member states to go ahead with integration and legislative projects when the required majority in the Council cannot be achieved; it is used only as

a last resort. It consists in creating a Unitary Patent, which would be automatically valid in the 25 member states of the EU, at the request of the patent owner and once the patent is granted by the EPO. The Unitary Patent is therefore a new option for the holder of a European Patent, who will choose between the classical “European” route of selecting the desired states for protection and a unitary protection covering 25 member states. During a transitional period of 12 years, the patents granted in German or French will have to be translated into English, and the patents granted in English will have to be translated into German and French. The translations will not have any legal effect; they are for information purposes only.

In a nutshell, the legal architecture of the Unitary Patent includes the “Unitary Patent Regulation” which consists in the introduction of the European Patent with unitary effect. Then comes the “Translation Regulation,” which describes the translation arrangements for the European Patent with unitary effect. These two regulations will be applicable for a maximum of 25 EU member states only on the date of entry into force of the Agreement on a Unified Patent Court (UPC) and only in the countries which will ratify it. As of January 2015, the Unitary Patent is therefore far from being operational, several details of its implementation having still to be framed and negotiated, and the number of countries it will actually cover is still unknown. These details are the medium-term challenge of the European patent system.

Medium-Term Challenge: Designing the Right System

“Challenge” is an appropriate wording, because the decisions that will be taken by policy-makers, hopefully before June 2015, will substantially affect the use of the Unitary Patent and the broad effectiveness of the European patent system. Two important facets have to be framed: the level and structure of renewal fees and the setting up of a centralized litigation system, orchestrated by the Unified Patent Court.

Renewal Fees... For Who?

The Unitary Patent renewal fee structure has been the subject of intense negotiations for several years. This is a highly sensitive issue, as it has financial consequences for both the EPO and the national patent offices (NPOs), as well as for all the stakeholders of the European patent system: inventors, patent attorneys, lawyers, or translators. The renewal fees paid to NPOs by the owners of European Patents are split into two equal parts. Half the amount stays in the NPOs budget, and the other half is transferred to the EPO (cf. Danguy and van Pottelsberghe 2011a, b, 2014). For the NPOs of large frequently targeted countries, the patents granted by the European Patent Office generate massive resources (more than EUR 100 million in Germany and about EUR 50 million for France and the UK), equivalent to several times the annual working budget of their NPO. Even for smaller countries, the income generated by the renewal fees of European Patents exceeds by far the budget of their NPO induced by the proceeding of national patents. With the Unitary Patent, renewal fees would be collected by the EPO, and half the amount would be distributed across NPOs. The “renewal fee” debate is therefore not only related to the level these fees, but as well to the distribution key (what percentage will be allocated to each country, according to which criterion?). Some NPOs defend the position of setting up very high renewal fees, as they expect it will have a minor effect on their income (most patent owners would opt for the current “European” route, and those who will opt for the “Unitary” route will generate more resource).

In summary, as of January 2015 a self-fulfilling prophecy is in the air, whereby the decision taken by policy-makers on the renewal fees of the forthcoming Unitary Patent will affect its success and its perceived effectiveness (cf. Danguy and van Pottelsberghe 2014).

Two renewal fee schedules can be considered: (1) summing up the current European Patent fees of several countries, for instance, those in which granted patents are most frequently validated, like Germany, France, the UK, etc., and (2) adding a fixed increment each additional year of the patent

European Patent System, Fig. 2 Potential renewal fee schedules for the Unitary Patent (Note: *Dashed lines* show fee structures which sum the fees of X countries that are the most frequently targeted for protection. *Plain lines* show the fee structures with fixed annual increment (described

between parentheses, starting fee at EUR 600 on year 6, and then an increment of 100 EUR (200 EUR, 400 EUR, or 1,000 EUR) each additional year. Source: Danguy and van Pottelsberghe (2014))

life. Figure 2 illustrates four alternatives for the former structure – the sum of fees of the first 2 (4, 8, or 12) countries – and four alternatives for the latter one. The UP(200) fee schedule could be considered as the most appropriate because it is simpler than the additive fee structures, and it corresponds to what the business sector is currently paying. Indeed, van Pottelsberghe and van Zeebroeck (2008) showed that the average geographical scope of protection is about four countries – UP(4) is similar to UP(200) – for the patents granted 15 years ago by the EPO. With UP(200), an applicant would pay cumulated renewal fees of about 15,000 EUR to keep its patent enforced for 20 years in the 25 EU member states. This absolute cost is affordable in relative terms, given the large geographical scope of protection provided by the Unitary Patent. The EUR 30,000 figure is similar to what a patent holder must be ready to pay in the current European patent system for less than 10 years of protection in 13 countries.

But the important question from the patent offices' viewpoint is whether the Unitary Patent would generate the same resources with its central renewal fees for the EPO and for all NPOs.

Danguy and van Pottelsberghe (2014) provide some answer, by simulating the net present value of renewal fee income for the average patents granted by the EPO, within the current system and within a two-layers system. Figure 3 shows the sensitivity of these simulations to different Unitary Patent fee schedules and to the expected share of Unitary Patents in total EPO-granted patents. Two observations might be drawn from these simulations. First, the higher the level of Unitary Patent renewal fees, the higher the total renewal fee income per average patent granted by the EPO, independently from the share of Unitary Patent. In other words there is a natural temptation to set high renewal fees. Second, with low Unitary Patent renewal fees, there is a U-shaped relationship between the share of UP and the total renewal fee income per average patent. This is due to the substitution effect between the two types of patent. The total renewal fee income collected by patent offices could actually be lower than the income in the current situation if the unitary patent system is not attractive enough (i.e., low share of UP) and has low renewal fees. At first glance these simulation results strengthen the argument for high UP renewal fees, so that they generate more

European Patent System, Fig. 3 Simulated total renewal fee income per average patent (Note: the bars represent the net present value of a patent granted by the

EPO and which would opt for the Unitary Patent route, taking into account its expected maintenance rate. Source: Danguy and van Pottelsberghe (2014))

income than under the current situation. However, very high fees would lead to a low use of the new unitary patent.

But even with aggregate renewal fee income stable or larger than the current system, patent offices logically worry about the share of this income that will be allocated to them. Danguy and van Pottelsberghe (2014) have simulated the revenue stream of national patent offices under the dual system. Their results show that only a handful of NPOs could be negatively impacted by the creation of the unitary patent system. Except for Germany, the budgetary losses for these patent offices are very low and only occur with relatively low shares of Unitary Patents in total EPO-granted patents. Improving the revenue prospects could also be achieved if the number of patents granted by the EPO increase and if national renewal fees would increase.

Which Design for the Unified Patent Court?

The second medium-term challenge relates to the design of the forthcoming Unified Patent Court (UPC), aiming at proceeding unitary patent litigations in Europe. In order to come into effect, the UPC Agreement must be ratified by at least 13 member states (including Germany, France, and the UK). A logical consequence is that the

Unitary Patent will cover only those member states where the UPC Agreement is in force. There is therefore a high probability that the Unitary Patent starts with much less than 25 member states, because converging to a common patent court denominator might prove to be complex and lengthy.

Indeed, the current national litigation systems are highly heterogeneous, reflecting important differences across national jurisdictions. For instance, some countries have technically qualified judges and others not, and the wage of judges is particularly high in the UK. Total litigation costs vary significantly across countries. The UK is by far the most expensive jurisdiction, with costs that are nearly as high as the cumulated costs in France, Germany, and the Netherlands. In case of multiple parallel litigations across jurisdictions, cumulated costs vary from 310 thousands euros before the four courts of first instance up to 3.6 million euros when taking account of the cost of appeal at second instance. Multiple litigations are particularly prohibitive in Europe, especially for individuals and SMEs, and can be more than twice as high as in the USA (see Mejer and van Pottelsberghe 2012). The challenges here will be to find a proper balance and a design that rally a majority of national litigation systems.

It is the responsibility of the Contracting States to set up the Unified Patent Court. A Preparatory Committee has been created in September 2013 to set out a road map for the establishment and coming into operation of the court. It has five main working areas, including the legal dimension, the financial sustainability, the human resource and training components, the design of the information system, and the facilities. It seems highly probable that there will be a central division of the Unified Patent Courts, with three Divisions, specialized in specific technological areas, and based in Paris, London, and Munich. Then, there will be regional divisions and local divisions, covering one to several countries, depending on the geographical areas and country size. The envisaged local divisions and their working language between parentheses would be based in “England and Wales” (English), the Netherlands (Dutch and English), France (French), Germany (German), and Belgium (Dutch, French, German, English). Envisaged regional divisions include one for Romania, Bulgaria, Cyprus, and Greece (all official languages plus French and English); one for Nordic countries (Denmark, Sweden, Finland, Estonia, Latvia, and Lithuania, with English as the main language); and one for Hungary, Czech Republic, and Slovakia (language undecided as of January 2015).

A Drafting Committee, composed of highly experienced judges and lawyers, is in charge of preparing the final draft. As of January 2015, the 17th version has been released (up-to-date information can be found on www.unified-patent-court.org). Areas of concern include a potential transitional regime, especially regarding an opt-out (from the Unitary Patent) provision; the possibility or not to bifurcate; the working languages at various divisional levels; the training, qualifications, and experience of judges; and court fees, recoverable costs, and numerous further procedural details. If bifurcation is allowed, there will be four different ways to enforce patent protection in Europe (Hilty et al. 2012):

1. Patents granted by national patent offices and enforced through national courts
2. European Patents granted by the EPO and enforced through the Unified Patent Court system
3. European Patents granted by the EPO and enforced through national courts
4. Unitary Patents granted by the EPO and enforced through the Unified Patent Court system

It will be possible to switch from option 3 to option 2 as long as the patent has not been subject to litigation in a national court. This new enforcement system and its flexibility will pave the way for more strategic behavior by patent owners. Unitary Patents might be allowed to bifurcate toward European Patents and hence might actually not be enforced only through the UPC. This bifurcation issue is, as of January 2015, still subject to change.

Longer-Term Challenge: Make It Work. . .

The European patent system which is being envisaged by policy-makers will include three layers of patents (national, European, and Unitary) and four enforcement mechanisms. Its cost in terms of renewal fees could be particularly high, not to mention the litigation costs and the complexity of the whole system. True, the Unitary Patent Package is in itself less complex and expensive in relative terms (i.e., per capita or per market unit), but it is being built on top of a two-layer system.

One can hardly disagree with the fact that this system, in its current format, will probably not better fulfill its ultimate objective of stimulating innovation in Europe: three layers make it more complex, and it might end up being quite expensive. This three-layer system is to be compared with a less expensive one-layer system in the rest of the world. But this is certainly not a reason to discontinue the Unitary Patent and Unified Patent Court projects. They are crucial for the construction of the European patent system, and much political power or courage will be needed to

achieve a coherent and effective system. In order to build an effective and truly European patent system, the following milestone will have to be considered:

1. National patent offices should stop granting patents on their own, which does not preclude playing an important role in their national innovation system, to continue to receive national priority filings and to perform search for prior art and preliminary assessments.
2. The European Patent should be void, and a phasing-out agenda should be established.
3. Small and medium entities should have substantially lower fees and litigation costs.

Abstract

The fight against cartels started in European Union since its foundation in 1957 and the passing of the Regulation empowering the Commission to enforce competition rules since 1962. However, anti-cartel policy was very ineffective in its early years from 1962 to 1980. It also had a lot of enforcement problems to uncover cartels until 1995. It was in 1996, when the leniency program was set up, when it truly became an increasingly effective policy. The leniency program is a mechanism by which infringing firms that have been active in a cartel can obtain fine reductions by providing hard evidence to the Commission about the existence and functioning of any cartel. The improving of the leniency program in 2002 and 2006, and the adoption of tougher fining policies and settlement procedure, has made cartel-busting policy much more effective in the last decade, but there is still much uncertainty to what extent anti-cartel policy will keep this trend of being more effective in the future.

EU Anti-cartel policy stages

The fight against cartels started in European Union (EU) since its foundation in 1957 and the passing of the Regulation empowering the Commission to enforce competition rules since 1962. Though in the last decade a clear advance in the detection, destabilization, and fining of cartels operating in the European Union has been noticed, the first years of anti-cartel policy were flawed. In fact, as Ordóñez de Haro et al. (2016) argue, four stages in EU anti-cartel policy can be highlighted.

First Stage (1957–1980)

The origin of the EU competition policy is found in the relevant provisions of the 1957 Treaty of Rome. The Article 85 of this Treaty (now Article 101 of the Treaty on the Functioning of the European Union) bans agreements among firms that restrain competition in the internal market.

The actual enforcement of these articles 85 and 86 became effective as of 21 February 1962, with the entry into force of the Council Regulation n° 17/62. This Regulation gave the Commission a central role as the authority charged with enforcing those articles, recognizing its power to open investigations, to adopt decisions and impose appropriate sanctions and remedies for the competition rules' infringements (McGowan 2009; Carree et al. 2010).

The enforcement system was based on the Commission's centralized control of the application of Article 85 and the requirement of prior notification by the parties of their agreements, decisions, and practices to the Commission which after examination of the notification could authorize them based on the proper exemptions contained in paragraph 3 of Article 85. This system caused serious delays in the procedural treatment and completion of the files and the consequent backlog of cases, since the Commission devoted a large proportion of its resources to deal with notifications.

To address this problem, the Commission tried to reduce the number of cases and to speed up the decision-making procedure by undertaking several initiatives, including the adoption and application

of several block exemption regulations, the use of the so-called comfort letters, or the introduction of notices on agreements of minor importance which do not have sufficient impact on competition.

At the end of this stage, in its decision in case *IV/29.595 – Pioneer Hi-Fi Equipment*, the Commission expressed its determination to shift its fining policy toward harsher sanctions for competition law infringements (Geradin and Henry 2005).

Seven cartels were sanctioned in this early stage of the European anti-cartel policy, totaling 55.53 million constant 2010 euro in fines (Ordóñez de Haro et al. 2016). The Commission just completed 0.4 sanctioned cases per year since 1962–1980 and imposed just fines of 600,000 euros per participating parent firm on average (constant 2010).

Second Stage (1981–1995)

It was a transitional stage during which the first consequences of that shift in Community fining policy were seen in the general level of fines imposed on cartels. The Commission reiterated its intention to move towards a tougher sanctioning policy in its Thirteenth Report on Competition Policy (1984).

Although there were no relevant legislative or institutional developments during this period, in December 1995, the European Commission published a draft notice concerning the non-imposition or mitigation of fines in cartel cases where undertakings cooperate in the preliminary investigation or proceedings in respect to an infringement. The subsequent adoption of this notice in 1996 represents a major milestone in EU competition law enforcement against cartels.

Over these 15 years, the Commission sanctioned 32 cartel cases. The total amount of fines exceeded 1122 million euro (constant 2010) in this period. The Commission just completed 2.1 sanctioned cases per year in this period and imposed fines of 4 million euro per participating parent firm on average (constant 2010).

Third Stage (1996–2005)

The introduction of the first leniency program in 1996 marks the start of a third stage which covers

all the steps taken toward the modernization of the EU competition policy up to 2005.

The first Community leniency program started on 18 July 1996. It was inspired by the US program in force since 1993, sought to encourage the breakdown of the “code of silence” among the members of the cartels and to become a successful tool that would significantly increase the effectiveness of competition policy (see Borrell et al. 2014).

Although this first leniency system is characterized by introducing some of the basic principles that would guide subsequent versions of the program, it lacked many enforcement details that were fixed in the 2002 and 2006 reforms of the leniency program.

Another significant change in this period was the publication by the Commission in January 1998 of its “*Guidelines on the method of setting fines imposed pursuant to Article 15 (2) of Regulation No 17 and Article 65 (5) of the ECSC Treaty*.” The European Commission, for the first time, provided a clear method for determining the final amount of a fine explaining the successive steps and criteria that would be taken in order to obtain that amount.

The creation of the first “anti-cartel unit” within DG IV (directorate later known as DG Competition), in December 1998, represented an important reinforcement of the particular fight against cartels. The progressive increase in resources culminated in the creation of a second “anti-cartel unit” in 2002. Nevertheless, the two anti-cartel units ceased to exist as they were conceived as a result of an internal reorganization of the DG Competition in July 2003. From then on, the resources and staff to combat cartels were then allocated to different units in several key sector directorates (Lowe 2008).

The numerous criticisms of the manifest deficiencies in the 1996 *Leniency Notice* yield to the publication, on 19 February 2002, of the new 2002 *Leniency Notice* which brought about significant changes to the procedure and specified requirements to benefit from the program (Arp and Swaak 2003; Borrell et al. 2015).

During the period covered by this stage, the provisions contained in the Council Regulation n°

17/1962 were valid until May 2004 when the *Council Regulation (EC) No 1/2003 of 16 December 2002 on the implementation of the rules on competition laid down in Articles 81 and 82 of the Treaty* entered into force. The most significant changes introduced by the Regulation 1/2003 mean the simplification of the administrative procedures and decentralization of the application of the competition rules in the EU. This reform implies that the system of notification and authorization was completely abandoned to be replaced by a directly applicable exception system. The Commission no longer had to deal with notifications from firms taking part in agreements, but the firms were directly liable of their conducts before the Commission, the National Antitrust Authorities, the European Courts, and the National Courts if they infringe the provisions of the Treaty reducing the Commission’s workload significantly (McGowan 2005).

From 1 June 2005 on, in response to the greater emphasis on combating cartels, a new Directorate in the DG Competition devoted exclusively to the fight against cartels became operational. The Cartels Directorate is responsible for carrying most of the cartel cases and plays a leading role, in close cooperation with the Directorate for Policy and Strategic Support in developing the policy to apply in the cartels arena.

Additionally, in 2005, a two-stage procedure is introduced by the DG Competition. So, from then on, all antitrust cases start with a first phase of investigation after which the Commission adopts a decision concerning the theory of identified harm and whether there is reason to pursue the case as a matter of priority. If the case is considered a priority, the Commission takes a decision in principle to initiate proceedings and then carries out a thorough investigation. This procedure is intended to spend less time and resources on cases that do not merit special attention.

To conclude this third stage, we should note the first initiative which tried to identify the main obstacles faced by the operation of a more efficient system of claims for damages which resulted from breaches of European Union competition laws: on 19 December 2005, the Commission

published the *Green Paper – Damages actions for breach of the EC antitrust rules* which includes the proposal of a series of measures aimed at encouraging victims of infringements of Articles 81 and 82 of the Treaty to exercise their right to claim for damages before Member States' courts (Pheasant 2006). Consequently, this initiative is designed to boost the interaction between public and private enforcement of antitrust rules (Diemer 2006).

In this period, a total of 44 cartel cases were sanctioned, 46% of them uncovered by a leniency application. Total fines imposed reach 5491.74 million constant euro. The Commission completed 4.4 sanctioned cases per year in this period (more than doubling the number of the previous stage) and imposed fines of 22 million constant euro per participating parent firm on average, multiplying the average fine by more than five times with respect the previous period.

Fourth Stage (2006–)

The last stage began in 2006, with several legislative reforms that aim to improve and consolidate those tools which proved to be valuable for fighting cartels, such as the sanctioning mechanisms, as well as the framework for cooperation between cartel participants and the Commission, in order to streamline procedures and to enhance the transparency and predictability.

The first of these improvements took place with the publication, on 1 September 2006, of the *2006 Fine Setting Guidelines*, which the Commission is currently putting in place, and they introduce some important new points (Barbier de La Serre and Lagathu 2013).

On 8 December 2006, the *2002 Leniency Notice* was replaced by the new *2006 Leniency Notice* (OJ C 298/17. 8.12.2006.). This is the second reform of the leniency program and aimed to provide for more clarity and transparency in its requirements and how to proceed in this program, as well as make it more attractive to potential cooperators (Sandhu 2007; Borrell et al. 2015).

In early July 2008, the Commission adopted the so-called Settlements Package. It consists of two documents: the *Commission Regulation*

(EC) No 622/2008 of 30 June 2008 amending Regulation (EC) No 773/2004, as regards the conduct of settlement procedures in cartel cases and the *Commission Notice on the conduct of settlement procedures in view of the adoption of Decisions pursuant to Article 7 and Article 23 of Council Regulation (EC) No 1/2003 in cartel cases*.

The *Settlement Notice* details the settlement procedure, interprets the new provisions contained in the *Settlement Regulation*, and provides further guidance on the first steps of the settlement procedure, the settlement discussions, the statement of objections, and the adoption of the final decision in such a procedure.

This package enables the Commission and parties to proceedings to follow a more simplified and simpler procedure when cartel participants, having seen the evidence in the Commission file, acknowledge their involvement in the cartel and their liability for the infringement (Mehta and Tierno 2008).

Finally, it is essential to stress the possible consequences for the fight against cartels that the adoption of the *Damages Directive* has and could have. Member States have until 27 December 2016 to transpose the provisions of the Directive into their legal systems (*Directive 2014/104/EU of the European Parliament and the Council of 26 November 2014 on certain rules governing actions for damages under national law for infringements of the competition law provisions of the Member States and of the European Union*). It remains to be seen whether the setup of an EU wide common framework for claiming private damages will make this policy even more effective in the near future.

The Commission's sanctioning activity during this stage was the most prolific of all with 53 cartel decisions until the end of 2014. Total fines imposed reach 17,739.87 million euro constant 2010. The Commission completed 5.9 sanctioned cases per year in this period and imposed fines of 62 million euro per participating parent firm on average (constant 2010), almost multiplying the average fine by three times with respect the previous period.

Experimental Law and Economics

Sven Hoeppe

Center for Advanced Studies in Law and Economics (CASLE), Ghent University Law School, Ghent, Belgium

Guest Researcher, Max Planck Institute for Research on Collective Goods, Bonn, Germany

Abstract

Experimental law and economics is the newest methodological development in law and economics research. Yet a lot of researchers – old and young – are not familiar with the foundations of the method. This may lead to skepticism. In this entry, I elaborate on the purpose of experiments and introduce building blocks of the method that tend to distinguish experimental law and economics from experimental methods in other disciplines. Moreover, I shortly discuss concerns about the external validity of the results obtained in a laboratory experiment. Finally, I introduce and invalidate the most common criticisms against experiments that most often advanced by scholars unfamiliar with the method and the discipline. As knowledge about the method's foundations is further spread, experimental law and economics will substantially contribute advancing the research frontier of the economic theory of law.

Definition

Experimental law and economics exposes theoretical research in law and in law and economics to methods from experimental economics, thereby testing existing theory, investigating observed

deviations from theory, establishing empirical regularities as the foundation of new theoretical constructs, and informing policy-making.

first reading for an audience interested – but yet unfamiliar – with experimental approaches to law (and economics).

Introduction

Not every lawyer, legal policy-maker, judge, or legal scholar conceives legal rules as a governance instrument that can be employed to coordinate and steer individual behavior in society. For those who do adopt such an *ex ante* perspective, however, it is of utmost importance to hypothesize about and investigate how law and individual human behavior are interrelated. To pierce the veil of ambivalent plausibility arguments and conflicting theories, it is even more important to understand what kind of behavior may be caused by alternative legal interventions.

Yet, legal scholars are often surprised and become quite reserved when they learn that a colleague is not extensively engaged in doctrinal legal scholarship, but rather adopts a social science approach. Caution usually rises to suspicion when the straying colleague conducts experiments, which seem rather alien to legal scholarship. But experiments can, *inter alia*, help to understand whether policy proposals – developed through, e.g., doctrinal legal scholarship – will function as intended.

Actually, experiments are not a novel method in legal scholarship. They have long been conducted in the law and psychology as well as in the criminology branches of legal research (Engel 2013a, b). Today, “[t]he only true novelty is the advent of experimental law and economics” (Engel 2013a, p. 7).

This entry is not written as a review of studies using an experimental approach to law and economics. Excellent reviews with a cornucopia of examples exist (cf. Croson 2002; Arlen and Talley 2008; Lawless et al. 2010). Rather, it is written with the intention to confront all too common misunderstanding about the experimental approach to law and to law and economics with information about the usefulness of experimental methodology for legal scholarship as well as policy-making. This entry should provide a good

Purpose

Generally speaking, in both disciplines, economics and law, there is a strong emphasis on deductive reasoning. Researchers start with a set of axioms, use rules of logic to manipulate them, and subsequently derive conclusions about their research question. For instance, in (neoclassical) economics, certain assumptions about individual behavior are used to mathematically model the theoretical construct “market” and to draw implications for the allocation of resources. As an example for deductive reasoning in law, one core assumption is that the law makes sense (*ratio legis*) and a lot of doctrinal legal scholarship is devoted to establish this inner logic of the law by means of interpretation and, furthermore, to match real-world facts to these abstract norms by analytical comparison (subsumption). Thus, doctrinal legal scholarship can conclude that legal consequences from an abstract, model-like norm are applicable to real-world facts.

A consequence of this heavyweight deductive reasoning is that theories become so complex and refined that simply observing natural data does often not address the pressing theoretical questions. Empirical tests of those theories are therefore significantly more difficult to perform. Experiments are one way to meet such a challenge (Croson 2002).

The more conducive purpose of conducting experiments in law, in general, and law and economics, in particular, is to exploit three advantages of the methodology. The first, and main advantage of experiments, lies in their possibility to solve the identification problem – the problem that arises when there may be bidirectional influence between dependent and independent variables that makes it difficult to separate cause and effect. For example, consider crime levels and the number of police: Does an increase in the level of crime cause a demand for more police, or do

fewer police cause more crime? Identification is notoriously difficult with field data. To establish causality outside of an experiment, at least three steps are necessary (Lawless et al. 2010). First, there needs to be a reliable association – or strong correlation – between the two variables. Second, one needs to credibly show that changes in the variable hypothesized to be the cause precede the supposed effect variable. Third and most problematic, other rival explanations for this observation (confounds) need to be ruled out, which also concerns the rather big problem of omitted-variable bias, where a driving variable is missing from the statistical model used for analysis. As a consequence, the effect of variables that enter the analysis is over- or underestimated.

To the end of separating cause and effect, a laboratory experiment generates an artificial environment in which participants are randomly assigned to different treatments. Random assignment facilitates control for unobservable individual differences among the participants. If carefully designed, the treatments in the experiment differ only by one dimension. Accordingly, if a treatment effect can be observed, it is a necessary result from the manipulation. With their distinguishing features – manipulation of one or more variables of interest, random assignment, and experimental control of other variables – experiments are specifically designed to test cause-effect relationships (Lawless et al. 2010). The very large degree of control can be used to generate a laboratory environment that tests theories and separates alternate theories that may not be separable with naturally occurring data (cf. Croson 2002).

The second main upside of laboratory experiments is their replicability. Because laboratory experiments are replicable, other researchers can reproduce the experiment and verify the findings independently. A stream of independent replications can test the robustness of findings. This is very difficult with field data because the environment is constantly changing such that each observation or dataset is just a snapshot of a certain combination of conditions.

Especially for legal scholars, experimentation brings about a third important benefit that is likely

to be equally important: experiments enable the study of problems that are hard or even impossible to observe in the field (Lawless et al. 2010), i.e., even if data are already available from other sources. How would addressees of a legal rule act if the existing rule would be or would have been replaced by an alternative rule? And what are the behavioral effects of different alternative rules that are under consideration for being implemented? Many a fact that is relevant for doctrinal lawyers and legal policy-makers are counterfactuals and never enter into field data (Engel 2013a). Experimenters can observe the unobservable (Falk and Heckman 2009).

Building Blocks

The basic logic of an experiment is to create different treatment groups (or experimental conditions) by manipulating one or more variables of interest, but always only one at a time, while every other variable is experimentally controlled for. The treatment without any variable change serves as the control group. This experimental manipulation creates desired differences between the groups, which enables the isolation of the different variables of interest, reduces confound, and ultimately facilitates identification of cause-and-effect relations. Participants are randomly assigned to these treatment groups. Randomization may occur for a lot of aspects in a specific experimental design. With regard to randomly assigning participants to experimental condition, random assignment, e.g., assures the initial comparability of the different experimental groups by equalizing the distribution of non-manipulated participant characteristics, such as age, income, gender, and education, across the experimental conditions. While participants are then being exposed to the experimental stimuli, their decision behavior is measured. Afterward, the different measurements can be compared across treatment groups. Because the only difference between the groups is their exposure to the treatment, any measured difference between the treatment and control groups can be attributed to the treatment.

Beyond this general categorization, experimental methodologies and their best practices – even within the social sciences – are quite different. Because of different underlying theories, experiments in a law and economics paradigm differ in their methodology from the earlier experimental approaches to law in psychology and criminology. Experimental law and economics is based on the methodology of experimental economics (cf. Hoffman and Spitzer 1985; Davis and Holt 1993; Friedman and Sunder 1994; Kagel and Roth 1995).

Although experimental economics pushes more and more to the field (Levitt and List 2007, 2009), the standard tool in experimental economics is the laboratory experiment. The lab offers the possibility to effectively employ controlled variation at relatively low cost (Hoffman and Spitzer 1985; Friedman and Sunder 1994). Decision environments can be controlled in ways that are very difficult to duplicate in the field. In the lab, the experimenter knows and controls participants' material payoffs, the order in which the different participants can act and interact, and – maybe most importantly – the informational situation for each single choice.

In experimental economics, one can generally differentiate four types of experiments for specific purposes: some experiments test theory, others investigate observed deviations from theory (anomalies), again others establish empirical regularities as the foundation of new theories, and finally experiments inform policy-making or test-bed new policy proposals (cf. Hoffman and Spitzer 1985; Roth 1986; Smith 1994). Each of these types faces particular methodological challenges (cf. Croson 2002).

The decisive difference between experimental economics – and by extension experimental law and economics – and the other experimental approaches to law involves a number of dimensions (cf. Davis and Holt 1993; Friedman and Sunder 1994; Engel 2013b).

1. Participants are exposed to a specific incentive structure that matches the payoffs in the theory underlying the experiment. The choices the participants make in the experiment determine

their compensation. This ensures that participants seriously contemplate their decision because value is induced (Smith 1976; Friedman and Sunder 1994). This is the main reason why experimenters in economics trust that “behavior in the laboratory is reliable and real: Participants in the lab are human beings who perceive their behavior as relevant, experience real emotions, and take decisions with real economic consequences” (Falk and Heckman 2009, p. 536).

2. Since real money is at stake, participants do not face a hypothetical, but rather a real situation. Note that in some cases and contradictory to established experimental economics, it may make a lot of sense to not incentivize a participant. This is the case, for instance, if the participant mimics the role of a judge who has, ideally, no monetary incentive in the single decision in real life (cf. Engel and Kurschilgen 2011).
3. The experiment is usually free from context. Economic experiments are very abstract to facilitate identification (cf. Ariely and Norton 2007). Firstly, context may add variance to the data and blur otherwise clear results. More worrisome, context may create systematically biased results or demand effects, i.e., when the participant tries to act according to the perceived expectations of the experimenter. As a result, the generated dataset would not be reliable. Lastly, avoiding context is, of course, a requisite when the underlying theories are also free from contextual cues. Note that context, however, may be a treatment variable as well. If so, the manipulation of context is the premier goal of the experiment.
4. Another distinguishing feature is that experimental economists generally take great care to not deceive their subjects. This is different in psychology experiments where deception is commonplace, although not undisputed (cf. Hertwig and Ortmann 2008). In experimental economics, the validity of the results depends on the link between expected payoffs and individual behavior. If participants are deceived about variables establishing this link, the validity of their decisions is

questionable. Moreover, experimental economists usually avoid tainting the participant pool. They are “concerned about developing and maintaining a reputation among the student population for honesty in order to ensure that subject actions are motivated by the induced monetary rewards rather than by psychological reactions to suspected manipulation” (Davis and Holt 1993, pp. 23–24). Admittedly, however, there is an intense, contemporary discussion about whether the costs of deception in experimental economics exceed the benefits (cf. Bonetti 1998; Hertwig and Ortmann 2008; Jamison et al. 2008; Alberti and Güth 2013; Krawczyk 2013).

5. Economic experiments are oftentimes interactive in nature. The reason for interaction between participants is straightforward. Economics experiments mostly employ some form of social dilemma game as experimental workhorse, and theoretical predictions focus on the results of social interaction.
6. Usually, experimenters in economics take great effort to ensure complete anonymity. As with all the other features, this is done with the aim to facilitate identification, i.e., to avoid confounds. To provide a counterexample, the experimentalist may not care about absolute anonymity, if the research question addresses reputation effects.
7. Often, the trials in the experiment are repeated to allow for learning and to study interactive dynamics.

These features facilitate what an experiment is ultimately all about: complete control. Only in an environment with extensive control can the claim become credible that an observed difference in behavior is indeed caused by the treatment manipulation and not merely the result of correlation.

Caution

However promising and rewarding the clear separation of cause and effect, experimenters face validity concerns. In general, the concept of validity refers to the extent to which an empirical study

produces accurate and credible data. Validity is assessed on three dimensions. First, internal validity refers to the extent to which the research design allows making inferences about the relationship of different variables. Internal validity involves that the experimenter must ensure that the choices faced by the control and treatment groups differ in the ways the experimenter hypothesizes, but do not differ in some other ways. This implies accounting for alternative explanations and omitted variables. Second, external validity speaks to the degree to which the research results can be generalized to a population beyond the particular study, i.e., to different people, different settings, different times, and also different measures. Third, construct validity refers to the extent to which the measures used to observe certain variables sufficiently capture the construct that the empiricist wants to study (cf. Lawless et al. 2010).

In order to isolate variables and to identify cause-effect relationships, experimentalists necessarily trade off external validity for internal validity. The artificial environment in a laboratory experiment allows the experimenter to make clean-cut inferences, but raises questions about its congruence with the social phenomenon that is to be studied. By design, what is measured in a laboratory experiment is only analogous to what the experimenter wants to understand (Smith 2010; Engel 2013b). Just because a hypothesis is falsified in the lab does not necessarily suggest that it will also be falsified in the field because there are so many intervening variables that cannot be controlled for. However, Plott (1982) counters concerns about external validity by pointing out that a theory will likely not predict outcomes in the real world if it does not (at least) predict outcomes in an idealized, controlled laboratory environment. Falk and Heckman (2009) argue that external validity problems are not a problem unique to experimental methodology.

Especially when legal scholars are on the hunt for cause-and-effect relationships between legal rules and individual behavior, they pay an increased price because they tend to distance themselves even more from the traditional doctrinal legal discourse (Engel 2013a).

Criticism and Concern

Particularly when scholars or members of another audience are unfamiliar with experimental work in general and the specific methodology in particular, a standard set of criticisms is often held against the experimental results.

Probably the most notorious objection involves limited external validity (see above). The gist of this critique is that the experiment cannot tell anything about the real world because the decisions are made in an artificial environment. As mentioned above, this is indeed reason to be very cautious to interpret experimental findings. However, this typical reason to disapprove of experimental results is misguided if the experiment satisfies the assumptions of the tested theory. Theoretical predictions rest on the assumptions of that theory irrespective of where the assumptions are met – in the lab or in the field (Plott 1982). The objection about limited external validity may have more grips, when the experiment concerns legal policy-making. In this context, an isolated cause-effect relationship matters less than entire institutions where certainly many of those relationships work with or against each other. Nevertheless, this implies the need to understand complex institutions by disentangling the muddle of causes and effects. Alternatively, legal experimenters may implement sequential designs that investigate behavior before and after the implementation of the entire legal institution (Engel 2013b). Lastly, empirical scholars know that likely none of the available methods will ever fully address reality. Falk and Heckman (2009) emphasize that it is not so obvious whether laboratory data or the field data are more informative. The scientific value of a method ultimately depends on the underlying research question. The empirical methodology notwithstanding, “eventually, reality is too complex, too little orderly, to be studied in an objective way” (Engel 2013a, p. 18). The concern about external validity certainly puts another emphasis on the complementary nature of different empirical methods, but it provides no grounds to completely dismiss one of them.

A second standard objection against experimental results concerns the participant pool.

Novices in experimental methodology often criticize the fact that experiments in law and economics more often than not rely on university students. They argue that students are certainly very different from the population in the real world and that they make decisions differently from professional decision-makers outside the lab. Fortunately, experimental research on this subject is on the rise. Oftentimes, there is no discernible difference in decision-making between students and professionals. If there is, however, students sometimes are more successful than professionals – although not always. There are a number of reasons why this objection seems to have a weak foundation (cf. Croson 2002; Falk and Heckman 2009). A student sample is as representative as any other sample, as long as it does not consist of only students with the same academic background, if this is part of the manipulation (cf. Frank et al. 1993, 1996). Most importantly, most often, the experiment is not reliant on any specific knowledge or experience. By contrast, there are also risks in bringing professionals to the lab. For instance, they may bring in incentives, knowledge, and experience that do not exist in the experimental design and therefore systematically bias results. Nevertheless, it is surprising that people often do not complain about seemingly weak participant pools in other areas of science. This is nicely illustrated with a not so ironic insight from Gary E. Bolton that he shared with me and others in July 2013: “In experimental economics, we typically begin our studies with students, pretty much for the same reasons medical experimenters begin with mice. First, they work cheap. Second, we can do what we want with them (within institutional rules). And third, they are genetically similar to real human beings”.

Another prominent critique of experimental work in law and economics is based on the size of the payoffs in the experiment. It is often argued that the size of payoffs is too small to induce meaningful behavior. However, experiments have been conducted with low and high payoffs and, in fact, have even tested differences between low and high stakes in experimental settings. All in all, there are very few differences on average behavior when the size of the stakes varies (Smith

and Walker 1993; Beattie and Loomes 1997; Camerer and Hogarth 1999).

Taken together, these common objections can be summarized as the “lack of realism” challenge. This notion, however, is based on an implicit assumption about the hierarchy of how relevant data are generated, with field data being deemed superior to data from the laboratory. Ultimately, however, the issue of realism is not a question of laboratory versus field data. The real issue is determining the best way to identify the causal effects in question. In this context, it is also important to stress that empirical methods are complements to each other (cf. Arlen and Talley 2008), not substitutes, as the discussion about the “lack of realism” suggests. Paradoxically, however, many of these objections also suggest conducting more experiments instead of fewer (Falk and Heckman 2009), because the critique itself is often based on a variable that can be manipulated in a new set of experiments to test the critique. This is, for instance, true for the aforementioned criticism that stakes are trivial and that participants are inexperienced students. However, this is not to suggest that experimentalists should not take these common concerns seriously. On the contrary, experimentalists should be their own most austere critics in order to prevent automatic, arbitrary experimental design that would threaten the credibility of experimental results.

In addition to these standard objections to the experimental method, Engel (2013a) specifically discusses sets of concerns prevalent in the legal academic arena. He distinguishes the rather diffuse concerns into five common categories of specific objections from legal scholars. To traditional lawyers, the experimental method appears to be (1) too scientific, (2) too individualistic, (3) too narrow, (4) too anxious, and (5) too small. While cleanly dissecting and acknowledging the foundations of these concerns, Engel (2013a) humbly refrains from completely resolving – or, for that matter, rejecting – them. Also, doctrinal legal scholarship and experimental law and economics can achieve more, if they work hand in hand.

Summary

This entry has introduced the purpose of conducting experiments – also in a legal context – and the basic building blocks of the experimental law and economics paradigm. A cautionary emphasis has been put on the validity trade-off that is inherent in all experimentation. Finally, criticism and objections have been briefly surveyed. These need to be taken – objectively – into account, if experimentalists care for the scientific value of their own method.

As legal scholars, “[w]e will quite likely have to live with some tension between science and doctrine, between individualistic and social constructions of legal problems, between the conditions for causal inference and lumpy institutional choice, between the responsibility for legal development and the competitive pressure of peer-review, between intuition and explication” (Engel 2013a, p. 29). Yet, experimenters can bring to light scientific knowledge that matters for the adoption of new rules, the further development of existing rules, and even the decision of concrete cases. Therefore, doctrinal legal scholars, lawyers, judges, and regulators should find it at least useful and relevant to have the generic knowledge available that has been generated in the laboratory.

In offering a mere introduction and a tertiary source, this entry necessarily stayed at the surface of what can only be called a fascinating methodological challenge. If this text kindled an initial spark among the audience, it was utterly successful. As is the case for the other empirical research methods, however, experiments are not to replace traditional legal discourse. Rather, they are promising and enlightening complements to doctrinal legal scholarship and the continuous evolution of the law and its economic theory.

Exploring the Deterrent Impact of Financial Supervisory Liability

Robert J. Dijkstra

Tilburg Institute for Private Law, Tilburg University, Tilburg, The Netherlands

Abstract

This entry provides a law and economics analysis of financial supervisory liability. It discusses the deterrent impact of financial supervisory liability by using existing law and economics theory and empirical evidence.

JEL Classification

K13

Introduction

Financial supervisory authorities have the complex task of supervising the financial markets to safeguard the stability of the system as well as to ensure an effective consumer protection. Their main activities consist of licensing of financial institutions (safeguarding entry to the market),

the ongoing monitoring of the health of financial institutions, sanctioning in case of noncompliance with law and regulations, crisis management, and conduct of business supervision (Lastra 2006). When they fail in their activities, they run the risk of being held liable by both third parties and the financial institutions subject to their supervision (Tison 2003; Athanassiou 2011).

In general, public authorities are liable in the same way as any private individual or company. This position follows from the historical fact that the Diceyan conception of the rule of law did not distinguish between public and private. Where a claimant wishes to sue another party, it should, in theory, not matter whether the defendant is a public authority or a private individual or company. It is therefore interesting to notice that nowadays more than 60% of the member states of the European Union have limited the liability of their financial supervisory authorities (Dijkstra 2012).

Why should financial supervisory authorities not be treated in the same way as any other defendant? What, if anything, justifies such a special treatment? The main policy argument, commonly used in favor of shielding financial supervisory authorities from liability is the “defensive conduct” argument. This argument assumes that the imposition of liability will inhibit the effective operations of a financial supervisory authority. The fear of being held liable is so severe that authorities start to act with too much caution when dealing with the supervisee.

On the other hand, submitting financial supervisory authorities to normal liability rules can be based on the preventive function of tort law, in which the threat of being held liable gives financial supervisory authorities incentives to perform their tasks with care (Dijkstra 2009). In this way, financial supervisory liability improves financial supervision by deterring the careless execution of financial supervisory tasks.

Both sides of the debate over the impact of financial supervisory liability can be examined using a law and economics approach. This entry explores the insights that existing law and economics theory and empirical evidence offer about the most likely deterrent impact of financial supervisory liability.

The remainder of the entry is structured as follows. Section “[Can We Apply Economic Analysis to Financial Supervisory Authorities?](#)” discusses the economic analysis of public authority liability. It makes clear to what extent traditional economic analysis can be applied to public authorities and, more specifically, to financial supervisory authorities. Next, section “[To What Extent Does Financial Supervisory Liability Deter?](#)” explores the impact of liability on the behavior of financial supervisory authorities by considering the context in which these authorities operate. It describes specific factors that are likely to influence the deterrent level of financial supervisory liability. As the actual deterrent impact of financial supervisory liability is at heart an empirical question, section “[Empirical Evidence](#)” presents an overview of the existing empirical evidence. Section “[Conclusion](#)” presents the conclusion of this entry.

Can We Apply Economic Analysis to Financial Supervisory Authorities?

The prediction of the effect of a liability rule is sensitive to assumptions about the underlying behavioral model (Spitzer 1977). The party subject to liability needs to be responsive to liability claims for liability claims to have an effect on their behavior at all. Traditionally, law and economics assumes that parties behave rational and want to maximize their utility. By internalizing the costs of their actions via liability rules, they will be motivated to take optimal care and/or engage in less dangerous activities, to prevent damage from happening (Faure 2008). This model seems to fit well to private companies. These companies are generally incentivized to produce at minimum average costs in order to maximize their profits. Faced with liability, they will take preventive measures in order to avoid being held liable and experience a decrease of profits. But what about public authorities? To what extent can the traditional law and economics model also be applied to public authorities? Their objective, unlike those of private companies, is not profit maximization. Legal literature is divided when it comes to answering this question.

Some scholars have argued that public authorities face budget constraints that could result in a more or less similar response to liability as private companies (e.g., Niskanen 1971; Rosenthal 2006). This perspective can be considered as an application of the rational choice model of bureaucratic behavior which assumes that a bureaucrat wants to maximize the size of her agency's budget. Maximizing the agency's budget would provide bureaucrats with other perks they value, such as, for example, prestige, compensation, and career prospects. It has therefore been suggested that public authorities may respond to liability with behavior approximating cost minimization (Kramer and Sykes 1987).

Other scholars are more critical regarding the application of the traditional law and economics model to public authorities. Rosenthal (2006) and Levinson (2000) argue that public authorities will respond to political rather than market incentives. When the political costs of diverting public resources to loss prevention are too high, the government will not make the investment even if it is economically justified (Rosenthal 2006). According to these scholars, liability cannot be expected to promote efficient governmental investment in loss prevention. One could however argue that liability imposes, at least, some political costs. After all, tort liability diverts public funds from other activities that are politically more profitable in terms of public perception and voter's appeal. Public authority liability may, at least potentially, thus create some political incentives to prevent careless behavior. We should however take into consideration that political incentives that may be powerful at the level of elected politicians and officials might not be that powerful for the nonelected bureaucrats employed in public authorities (Dari-Mattiacci et al. 2010).

The idea that liability results in some political incentives might not be completely true when it comes to financial supervisory authorities. While most public authorities are funded from a central, governmental budget, financial supervisory authorities are, more and more, funded from fees imposed on the supervised institutions. This means that any increase of supervisory costs due to law cases against financial supervisory

authorities is ultimately not fully born by the taxpayer but more and more by the financial industry, thereby diluting the impact of political incentives. One could thus question the ability of liability to motivate behavioral changes given the financial authorities' ability to pass (all or at least a significant part of) their costs on to the financial institutions subject to their supervision.

In addition to market and political incentives, one might also want to consider the effect of reputational deterrence (Gold 2016). Reputational deterrence occurs because employees want to protect their organization's pride as a form of protecting self-identity. They thus avoid actions that could expose their organization to lawsuits that can negatively affect their organizational pride. The question remains whether it is the lawsuit or the incident itself that generates negative publicity and hence negatively affects reputation.

There is obviously no easy answer to the question whether and how financial supervisory authorities respond to liability claims. Financial supervisory authorities are probably not solely self-interested or only motivated by reputational incentives, political incentives, or incentives provided by liability (Dijkstra 2010). Their behavior is likely to be influenced by their employees' own morality, social norms, organizational culture, and much more. So, at best, the behavioral consequences of imposing damages liability on public authorities are uncertain. However, the fact that more governments limit the liability of their financial supervisory authorities based on behavioral consequences makes it at least appropriate to investigate the deterrent impact of financial supervisory liability.

To What Extent Does Financial Supervisory Liability Deter?

Conditions for Deterrence

For liability to effectively deter unlawful conduct, a number of conditions have to be met. First, the targets of liability rules must be aware of and understand the rules. Secondly, they need to have the willingness to follow the rules. This will, among other factors, depend on the deterrent

level of that liability claim. In general, the deterrent level of a liability claim can be defined as the capacity to dissuade a potential tort-feasor from behaving carelessly and depends on the one hand on the size of a sanction and on the other hand on the probability of being sanctioned (Baker et al. 2004). In combination, these two variables constitute the expected sanction, and the expected sanction is what influences behavior. The more the public authority believes that it will be sued and punished in a way that has a significant impact, the greater the deterrent effect. The third condition that needs to be met is the ability to conform conduct to the requirements of the rules as actors make decisions about their activities (Robbenolt and Hans 2016).

Various circumstances, often arising from the context in which actors operate, can influence these conditions resulting in either over- or under-deterrence. In a situation of under-deterrence, the deterrent capacity of liability is too low to motivate parties to take optimal care while exercising their activities. In other words, potential tort-feasors do not internalize the full costs of their behavior. The opposite occurs in a situation of over-deterrence. In this case, the fear of being held liable is so severe that a potential tort-feasor engages into so-called defensive conduct. Defensive conduct refers to any act or omission that is performed solely to avoid liability or to provide a good legal defense against a liability claim because of over-deterrence (Hauser et al. 1991).

To determine whether liability can adequately deter undesirable activities, encourage defensive conduct, or has no impact at all, it is necessary to take a closer look at the specific context in which financial supervisory authorities operate.

Willingness to Follow the Rules: The Probability of Being Caught, Sued, and Held Liable

The higher the probability of being caught and sued, the more likely it is that liability will deter potential tort-feasors. So, what is the probability that a financial supervisory authority is caught, sued, and held liable by the court for careless behavior resulting in damage? To answer this

question, we need to make a distinction between two categories of financial supervisory liability (Tison 2003).

First, financial supervisory authorities can be held liable by third parties. In most cases, this will happen after the bankruptcy of a financial institution. Creditors of the financial institution will then try to receive compensation for their losses by suing the financial authority based on shortcomings in performing their tasks. Without a bankruptcy of a financial institution, the financial supervisory authority does not face a big risk of being held liable as the victims will first try to get compensation from the primary wrongdoer, the financial institution itself. The probability of third-party financial supervisory liability depends thus mainly on the probability of a financial institution going bankrupt.

Under normal circumstances, the chances of a financial institution going bankrupt are relatively small. Even when a financial supervisory authority acts negligent while performing its supervisory tasks, it is not likely that that causes financial institutions to go immediately bankrupt. It merely increases the probability of defaults in the future. The opposite is also true. Despite thorough financial supervision, there is still a possibility that a financial institution goes bankrupt. The bankruptcy of a financial institution depends namely on a wide variety of factors and circumstances of which financial supervision is merely one. The chances of an actual bankruptcy are further reduced by the fact that governments will most likely intervene when a financial institution is “too big to fail.” In the past, we have seen that governments will nationalize these troubled financial institutions.

But even if a financial institution goes bankrupt, there is a mechanism that limits the liability risk for a financial supervisory authority. Most countries, namely, have a deposit guarantee system in place that offers compensation to depositors in case a financial institution goes bankrupt (Dijkstra 2009). Only if their losses are (much) greater than the compensation from the deposit guarantee fund will they have an incentive for holding the financial supervisory authorities liable. This group of persons is likely to be limited as

a deposit guarantee fund, with a minimum coverage level of EUR 100,000, normally covers 95% of all deposits (Joint Research Centre 2010). We can thus conclude that the risk of third-party financial supervisory liability is limited, even if financial supervisory authorities are performing their tasks in a negligent manner.

The second category of financial supervisory liability seems to be more straightforward as it concerns a direct relationship between the financial supervisory authority and the victim (e.g., the financial institution subject to supervision). In this case, it is more likely that negligent behavior of a financial supervisory authority results in damage that is immediately detected by the victim. Liability in this category will mainly arise from wrongful actions, in most cases acting too strictly, aimed at the financial institutions. Examples include the wrongful rejection of a permit to operate (market entrance) and a wrongfully published sanction resulting in (reputation) damage for the financial institution. Compared to third-party liability due to too lenient supervision as discussed above, the probability of being held liable by financial institutions due to too stringent supervision is larger.

For both liability categories, it is important to mention that they are affected by the so-called availability heuristic. This behavioral economics term refers to a mental shortcut that relies on immediate examples that come to a person's mind when thinking about a specific topic. Judgments about the probability of being held liable are thus often affected by whether a recent event comes readily to mind. The key issue is thus not the objective risk of being sued and held liable but the perception of the severity of the risk that this will happen (Baker et al. 2004). That might also explain why the Dutch financial supervisory authorities changed their mindset about the threat of liability leading to defensive conduct after a few lawsuits arising from the financial crisis (Dijkstra 2017).

Willingness to Follow the Rules: The Size of the Sanction

As a general starting point, damages should fully compensate the victim for his losses because only then will the injurer internalize the negative

externalities that he has caused (Visscher 2009). So, to provide financial supervisory authorities with the correct incentives to behave carefully, damages should be based on the social losses caused by their negligent behavior. A number of factors influence the size of the sanction that financial supervisory authorities face when being held liable.

First, there is the earlier mentioned deposit guarantee system. This system compensates a significant part of the damage of depositors in case a financial institution goes bankrupt. Consequently, financial supervisory authorities will not face the full costs of their careless behavior. The existence of a deposit guarantee scheme is thus likely to decrease the deterrent level of third-party financial supervisory liability (Dijkstra 2009).

Secondly, financial supervisory authorities might have specific clauses in place that shield them from paying the full amount of damages themselves. These clauses often relate to all categories of financial supervisory liability. The Dutch financial supervisory authorities have, for instance, a safeguard clause in place with the Dutch Ministry of Finance. This safeguard clause limits their financial risk from liability claims to maximum 10% of their budget. In case a liability claim exceeds this maximum, the Dutch Ministry of Finance will cover the remainder of the damage compensation. This means that the Dutch financial authorities will then not internalize the full amount of the damage they have caused.

Although not all financial supervisory authorities have formal safeguard clauses in place, it is likely that implicit safeguard clauses exist. It is not realistic to assume that governments would endanger financial supervision by allowing liability claims to fully consume the budgets of their financial supervisory authorities. Furthermore, the fact that financial supervisory authorities are more and more funded by fees imposed on the financial institutions subject to supervision makes it less likely that the authorities will face the full monetary consequences of their careless behavior as they can pass their costs on to the financial industry.

In addition, financial supervisory authorities may also have the possibility to insure the

financial risks from liability claims, as is the case with the Dutch financial supervisory authorities. In general, law and economics theory predicts that liability insurance will reduce the incentives for potential tort-feasors (Cooter and Ulen 2016).

Awareness and Understanding of the Rules

Potential tort-feasors must be aware and understand the legal rules in order for liability to deter negligent conduct. The traditional economic model assumes that there is no uncertainty regarding the level of care needed to be compliant with the legal rules (Cooter and Ulen 2016). In the real world, however, legal standards are often uncertain. To determine the optimal level of due care, courts need complete and accurate information on the costs of care and the expected costs of accidents for each level of care. However, data necessary to set the optimal level of care will often be unavailable. In addition, courts will not always be able to properly observe the actual level of care exercised by the tort-feasor due to measurement errors, insufficient evidence, and misrepresentation about the actual level of care. Thus, only during a trial, when parties present the facts of the case, is the due level of care established in a more precise way. As a result, tort-feasors exercising a certain level of care might not know *ex ante* whether or not they will be found negligent.

This also applies to financial supervisory authorities. From case law and literature, it becomes clear that the standard for financial supervisory authorities under a negligent liability rule is “reasonable care.” This standard is surrounded by uncertainty, because financial supervisors have discretionary powers to fulfill their supervisory duties and face the difficult task of considering both the interests of the supervised institutions and the individual members of society. Furthermore, there are relatively few tort judgements in the area of financial supervisory liability which makes it difficult to know the exact content of the standard of care. What does this mean for the deterrent effect of tort law?

Uncertainty regarding the level of due care changes the deterrent impact of legal rules by creating two opposing effects (Craswell and Calfee 1986). The first effect is an incentive to

over-comply. Tort-feasors will, in this situation, take more care than is required by the legal standard of care to increase the chance that they will not be held liable. However, uncertainty also creates a chance that a tort-feasor will not be held liable, thus reducing the incentives to comply with the legal standard. The question thus created is which effect will prevail. Standard law and economic theory predict that over-deterrence (and thus defensive conduct) will occur (Craswell and Calfee 1986). Scholars have argued that this is even worse when a public authority is involved due to the fact that, unlike private tort-feasors, a public authority typically balances two external costs, as it does not bear the costs of over-precaution. Public authorities are therefore much more quickly inclined toward taking excessive care (e.g., De Geest 2011; De Mot and Faure 2012).

The existence of uncertainty regarding the standard of due care for financial supervisory authorities might explain why politicians and many others fear over-deterrence and thus defensive conduct on the side of financial supervisory authorities. By limiting the liability of financial supervisory authorities to cases of gross negligence and/or bad faith, they argue that the standard of care becomes clearer and hence would result in limiting over-deterrence and thus defensive conduct.

Ability to Conform Conduct

The third and last condition that needs to be met in order for liability to effectively deter is the ability of parties to conform their conduct to the requirements of the rules as they make decisions about activities in which to engage, the extent and location of those activities, and any precautions to undertake (Robbenolt and Hans 2016).

Law and economic scholars view organizations and thus also financial supervisory authorities as single economic and organic entities. However, it is important to note that public authorities themselves do not commit negligent acts; their employees do. Financial supervisory liability involves the imposition of liability on the organization itself due to the harmful behavior of its employees. Making the financial supervisory authority liable may however fail to provide

its employees with sufficient incentives to act carefully, as the sanctions imposed on the organization might not reach the responsible employees (Dijkstra 2009; Dari Mattiacci et al. 2010). The question of whether incentives are transferred from the financial supervisory authority to its employees is a manifestation of the well-known agency problem between organizations and their employees. The challenge for financial supervisory authorities is, therefore, one of overcoming principal–agent problems.

While most of the financial supervisory authorities have mechanisms in place to mitigate these problems (e.g., reward policies, recruitment policies, internal and external audits), it is realistic to assume that principal–agent problems dilute, to some extent, the deterrent effect of financial supervisory liability.

Over-deterrence, Under-deterrence, or No Effect at All?

The various factors from the previous paragraphs are more likely to result in under-deterrence than in over-deterrence. While a vague standard of care is likely to result in over-deterrence, several other factors contribute to under-deterrence. First, the threat of third-party liability seems to be limited as this liability category follows, in most cases, the bankruptcy of a financial institution which does not occur often. Second, in case a financial institution goes bankrupt, the existence of a deposit guarantee scheme limits the potential damage of third parties and thus also the potential number of claimants. Third, the existence of explicit or implicit safeguard clauses and the possibility to insure the financial risk will further limit the financial consequences for the negligent behaving financial supervisory authority mitigating the deterrent effect of liability. Furthermore, it is questionable whether the financial supervisory authority can effectively transfer the incentives from liability to their employees. Under-deterrence is therefore most likely to occur, thereby questioning the risk of defensive conduct.

It is however difficult, if not impossible, to accurately estimate the deterrent impact of financial supervisory liability from a theoretical perspective. Whether the imposition of liability

promotes more effective financial supervision, encourages defensive practices, or has no discernible effect is at heart an empirical question. The next paragraph presents therefore the outcome of empirical research on this topic.

Empirical Evidence

There is hardly any empirical research on the deterrent impact of financial supervisory liability available. The few studies that exist do show however that defensive conduct is not likely to occur, making under-deterrence more realistic.

Van Dam (2006) asked several Dutch national supervisory authorities, including the financial supervisory authorities, whether their behavior is influenced by the fear of liability. At that time, the supervisory authorities claimed that they did not change their policy out of fear for liability claims. Based on their statements, Van Dam concluded there was no indication for defensive conduct. A couple of years later, the financial supervisory authorities, most likely due to the influence of increased liability claims because of the financial crisis, seemed to have changed their minds and argued for a limitation of their liability. The attitude of the Dutch financial supervisory authorities toward liability claims changed since the financial crisis had put them more into the spotlights. This could indicate that perceptions regarding liability are likely to change when confronted with more liability claims that generate (negative) publicity.

In another study, Trebus and Van Dijk (2014) carried out interviews with four senior employees of the Dutch Financial Markets Authority to examine the impact of liability on their behavior. None of the respondents mentioned any form of defensive behavior in response to liability claims nor did they feel threatened by liability in the exercise of their daily supervisory activities. Based on their research, Trebus and Van Dijk concluded that financial supervisory liability has almost no impact on the behavior of financial supervisors.

A more comprehensive empirical research was carried out in 2015. Dijkstra (2017) conducted a

survey among 500 financial supervisors active in financial supervisory authorities in the member states of the European Union. The majority of the respondents classified the impact of financial supervisory liability as either neutral or positive. The findings of this study therefore imply a modest degree of deterrence. Furthermore, the relative neutral or positive attitude suggests that financial supervisors do not consider financial supervisory liability a burden for executing effective financial supervision. In addition, the survey did not find differences between those respondents who perceive the liability of their organization as limited and those who do not. This suggests that limiting financial supervisory liability does not affect perceptions of the impact of financial supervisory liability or possibly even the behavior of financial supervisors. Therefore, the study calls into question the widely accepted argument of defensive conduct as a reason for limiting the liability of financial supervisory authorities.

This limited empirical research can, however, not be seen as overwhelming empirical evidence regarding the impact of financial supervisory liability. One could further argue that the value of these types of studies (surveys) is limited because they measure perceptions and not actual behavior. They do however raise serious doubts on whether financial supervisory liability will result in over-deterrence and thus defensive conduct.

Conclusion

The theoretical literature is divided regarding the deterrent impact of financial supervisory liability. The picture that emerges from this entry, while lacking detail in many spots, should at least inspire skepticism about the risk of over-deterrence. Our theoretical analysis shows that there are many factors influencing the deterrent level of financial supervisory liability. Most of them tend to lead to under-deterrence, making it hard to believe that financial supervisory liability will result in over-deterrence. This outcome is supported by limited empirical evidence showing only a modest degree of deterrence.

External Incentives

► Intrinsic and Extrinsic Motivation

Externalities

Andrew Torre
School of Accounting, Economics and Finance,
Deakin University, Melbourne, VIC, Australia

Abstract

Externalities and court output are closely related since the primary economic function of the courts is to price and thereby internalize external effects in missing markets. This is achieved using the complementary technologies of torts and criminal law. An externalized cost can be broken up into two components, the cost imposed on the unconsenting victim and the cost imposed on wider society, such as insecurity and fear of further random episodes of the same event. Damages awarded to the victim in torts, and criminal punishment inflicted upon the offender, value and internalize the first and second components, respectively. Unless damages and punishment accompany each other, the externality will not

be fully internalized. In addition, punishment produces absolute general deterrence, which is a positive externality, and in this sense negative and positive externalities are mirror images of each other, or perfect complements, in a legal economics framework. This framework also establishes the theoretical underpinnings and basis for valuing joint court output in the civil and criminal jurisdictions.

Synonyms

[Externalized benefits](#); [Externalized costs](#)

Definitions

Externalities are classified as either negative or positive.

A negative externality arises when a decision maker does not bear all of the costs of his or her decision. As a consequence, some costs are externalized onto others without compensating them. An example would be burglary. The private cost to the burglar is the dollar value of the alternative use of his or her time and the expected penalty if caught and convicted. However, the social cost is much higher. First, there is the cost imposed on the victim in the form of property damage and/or loss, and in addition, intangible costs such as fear of further incidents and distrust of others, leading to excessive precautions being taken to protect the property. Second, people other than the victim also incur the fear and self-protection costs. The social cost of burglary therefore exceeds the private cost.

A positive externality arises when a decision maker does not capture all of the benefits of his or her decision. If the burglar is caught and convicted, then a judge will impose punishment in the form of a monetary, noncustodial or custodial penalty. The sanction produces a positive externality in the form of absolute general deterrence, because punishing the burglar deters others from similar behavior in the future. There is a private benefit to the victim, since the penalty may prevent burglary of his or her property in the

future and a much wider benefit to everyone else for the same reason. Therefore, the social exceeds the private benefit.

Introduction

A useful starting point for this essay is to conceptualize the legal system as a production process. In economic theory, a production function summarizes the relationship between the inputs, labor and capital, and the corresponding outputs for a given technology. Similarly, the legal system utilizes a given technology to produce several intermediate outputs and two distinct final outputs from a bundle of inputs. Lawyers distinguish between civil and criminal cases. A case and its ingredients constitute the raw materials of the legal system. For a civil matter these are the cause of action(s), the nature and quality of the evidence and the services of solicitors and barristers, and in a criminal case the offense(s), police, prosecutor, solicitors, and barristers' services. The two final joint civil and criminal court outputs that can be valued in dollar terms are damages and absolute general deterrence, respectively. The latter is jointly produced by the police and courts. Intermediate civil outputs include the court's finding for the plaintiff or defendant, orders of specific performance, injunctions, and in the case of family law matters, custody and property division decisions, for example. Intermediate criminal outputs are bail decisions, committals, trials, sentencing hearings, and the verdict. Absolute general deterrence means that as a consequence of the police clearing up offenses and courts inflicting punishment in the form of fines and jail time on convicted defendants, the social cost of crime will be lower in the future. This is because some prospective offenders at the margin of legal and illegal activity will desist from the latter, since the risk of expected punishment does not make it worthwhile. For this reason, punishment that deters is sometimes called utilitarian punishment (Bagaric 2000). Society is unequivocally better off and therefore net happiness increases. It would only be the case that punishment never deters some people other than the offender, if

penalties for serious offenses were abolished and their incidence did not increase. This seems highly improbable.

The technology of the legal system comprises three interrelated parts. First in common law systems, there is a body of complex past decisions called precedents or more generally the common law. Its birth approximately occurred with the establishment of the royal courts or *curiae regis* by Henry 11, who reigned from 1154 to 1189 (Mendelson 2010, p. 12). Second, the stock of judicial precedents is supplemented by a voluminous compendium of statutory-based law. The equivalent in civil law systems is a set of codes, modeled on the classical Roman law. However, unlike in common law jurisdictions, codes in civil law ones are the most authoritative source of law with judicial decisions being subservient to them. Third, there are the judges who create, interpret, and apply the law.

A production process is said to be efficient if the cost of using the inputs to produce the outputs is minimized; the same reasoning applies to the legal system; damages and deterrence can be supplied efficiently or inefficiently, for a given technology. However, this use of the term efficiency is generally different from the way it is used in the law and economics literature. In the latter, it tends to be employed by some writers when analyzing bodies of substantive law, in particular torts, criminal, contract, and property law (Landes and Posner 1981, 1987; Cooter 1985; Posner 1985, 2010). According to this paradigm, torts legal rules, for example, are efficient if they prospectively minimize the sum of expected damage plus precaution or avoidance costs (Cooter and Ulen 2004, Kaplow and Shavell 1999, Posner 2010). This hypothesis has stimulated the production of a large critical literature. For example, applying it to legal negligence would necessitate the court engaging in a fairly complex calculation exercise, in its inquiry as to whether the injurer had taken cost-effective precautions against the legally caused harm. Hayek's fundamental contribution to the socialist calculation debate in the 1920s and 1930s, in which he argued vigorously against central planning as a substitute for the market mechanism in allocating scarce resources between

alternative uses, was to show that localized, widely dispersed information precluded rational economic calculation on the part of economic planners (Hayek 1945). Similarly, a judge asked to undertake an efficiency cost-benefit calculation would find him- or herself in the same position as a central planner. This led Leoni and Hayek to an alternative characterization of the legal system, particularly common law dynamics, as a spontaneous order derived from the adjudication of individual claims and not the result of human design that aims at any particular end such as wealth maximization or efficiency (Leoni 1972; Aranson 1988; Hayek 1973, Volume 1; Cheren 2012). It seems that this approach fits more comfortably with rights based non-efficiency theories such as corrective justice, which Burrows (1999) defines as “protection of arbitrary alterations to the initial distribution of property rights by restoration of plaintiffs as far as possible to their ex-ante position, thereby preventing defendants from benefiting from the actual harm they have caused.”

The Economic Nature of Externalities and Their Relationship to Law

The subject matter of this essay is externalities, which can be broadly classified into negative and positive (Gans et al. 2012). Textbooks commonly use pollution as an example of the former, and research and development expenditure is common for the latter. A firm that produces steel incurs private costs of \$100,000 (raw materials and labor costs). Residents living across the road suffer from asthma as a consequence of pollution from the factory and incur medical costs of \$10,000. While the total social cost of producing steel is \$110,000, market forces will only reflect the private cost of \$100,000, since the manufacturer externalizes \$10,000 on to the residents. Consequently, market forces overvalue steel and too much is produced and consumed. As the fundamental cause of the problem is an absence of enforceable property rights in the airspace through which the pollution is transmitted, property law provides the basis for a market or private solution.

If either a court or the legislature vests property rights in the airspace to the firm, then the affected residents may be able to bribe the firm to cut back its emissions of pollution in return for a payment. Alternatively if the residents own the airspace, then the firm may be able to successfully negotiate to pay the residents to accept a mutually agreed upon level of pollution. Irrespective of the initial assignment of property rights, transaction costs may impede a bargain from being successfully consummated (Cooter and Ulen 2004; Posner 2010). Sources of high transaction costs include emotional or psychological conflict between the parties, information about the damage cost not being fully available to both parties, disagreements about the cost estimates making it difficult to negotiate a price, or too many parties to deal with (Cooter and Ulen 2004; Posner 2010). The more people that are involved, the less likely it is that an agreement acceptable to everyone will be reached. If bargaining fails, then the standard solution advocated is to force the firm to take into account the \$10,000 externalized cost when it is computing its profit, by imposing a tax or a fine equal to this amount (Gans et al. 2012). This is only efficient if it would be more expensive for the affected residents to take corrective action themselves, for example, by relocating.

In contrast to pollution, research and development expenditure produces a positive externality; consequently market forces will undersupply it. Unimpeded market forces will lead private firms to underinvest in knowledge creation because they are unable to fully appropriate the benefits of their investment. For example, in the case of a new drug that is very expensive to develop, it would be relatively easy for a competitor to discover its molecular formula through reverse engineering. As a consequence drugs will be undersupplied and overvalued (priced too high) by market forces. Traditional solutions are government subsidies, and patenting of the intellectual property embodied in the drug, to rectify the market failure.

These two examples suggest some sort of relationship between legal technology, in particular physical and intellectual property law, and externalities; however, the relationship is at best

cursory. Yet using a legal economics framework, it is possible to see the centrality of torts and criminal law to the problem at hand, and their relationship to the two externality types, in a different light. Torts and criminal law are very much concerned with defining and internalizing negative externalities, and in addition, perhaps counterintuitively, criminal law generates a positive externality. An externalized cost can be broken up into two components, the cost imposed on the unconsenting victim, for example, violation of bodily integrity following a sexual assault, and the cost imposed on wider society, for example, insecurity and fear of further random episodes of the same event. A finding in favor of the victim, followed by an award of damages in torts, values and internalizes the first, while a guilty verdict, followed by punishment, values and internalizes the second component. Full internalization occurs because the injurer is forced to confront both components of the externalized cost. As well, punishment produces deterrence, which is a positive externality or externalized benefit. Since an award of damages without a criminal penalty will only achieve partial internalization, economically, torts and criminal law are complementary technologies, not substitutes.

Historically, this was not always the case, because there were alternative ways for a victim to pursue justice for the same wrongful act, a choice between “compensation or vengeance” (Seipp 1996). If compensation was chosen, it would be paid to the victim and the king, so that the externalized cost would be fully internalized. However, most victims tended to choose vengeance since not many wrongdoers had sufficient wealth to pay the necessary compensation and during the Middle Ages (fifth to the fifteenth century), revenge was considered a “higher right” (Frankel 1996). Professor Mendelson classifies modern torts into three categories: statutory, trespass, and action on the case (Mendelson 2010). Trespass comprises battery, assault, false imprisonment, variants of statutory trespass, trespass to land, trespass to goods, and cattle trespass, while case comprises, *inter alia*, deceit, detinue (unlawful deprivation of possession), conversion, nuisance, libel, slander, defamation, negligence,

passing off, and a series of miscellaneous intentional torts of action on the case for personal injury (*idem.* p. 8). These causes of action protect a multiplicity of entitlements, which include physical integrity or immunity from direct and indirect injury (battery and negligence); the right to use land, light, air, running water, the sea, and its shore (trespass to land, private and public nuisance, and negligence); and the right to corporeal and intellectual property (conversion, detinue, trespass to goods, passing off, misrepresentation, and injurious falsehood) (*idem.* p. 6). All of these causes of action have equivalent counterparts in the criminal law.

Two Illustrations of the Close Nexus Between Externalities and Torts and Criminal Law

Two detailed examples are now used to illustrate the themes explicated in this essay. The first is the case of a property owner who proposes buying an airspace lot above the roof of an apartment block, which is adjacent to his top floor apartment. The entire apartment block is owned by one person and the objective of the property owner’s purchase is to preserve his unimpeded city views. If this market transaction fails and the adjacent owner in any way obstructs the property owner’s view, she will externalize an uncompensated cost onto him. As in any market transaction, the property owner will have a maximum willingness to pay for unimpeded views and the apartment owner will have a minimum or reservation price that she will require before relinquishing the right to her air space lot. For a deal to be consummated, the negotiated price will need to lie between these two values. The two most likely stumbling blocks to a successful outcome would be agreeing on a mutually acceptable price and/or animosity between the parties. These potential problems are called transaction costs and can prevent the completion of a successful bargain that would internalize the externality (Cooter and Ulen 2004; Gans et al. 2012; Posner 2010).

If bargaining fails and the apartment owner subsequently erects a structure on her roof without

in anyway invading the property owner's airspace, then even though she is externalizing a cost on to him, no common law legal right would have been violated. This is because, as reaffirmed by the English House of Lords in 1997 in the case of *Hunter v Canary Wharf Ltd.*, the law of torts does not recognize a legal right to a view from one's property (Mendelson 2010, p. 668). If however the property owner ignored his neighbor's refusal to sell her air space lot and attempted to coerce her into changing her mind, by, for example, entering the balcony of the neighbor's top floor apartment without her permission, then this would infringe a legally recognized right. This externalized cost would be actionable at common law for trespass to the neighbor's land (Mendelson 2010, p. 138). While an injunction ordering the tortfeasor to desist from the trespass would enforce the neighbor's property right, it would not in the economic sense force the property owner to confront the full costs of his decision to bypass the market. The first step in achieving this, i.e., fully internalizing the externality, would be a finding for the victim and an award of compensatory damages, which measures the court's assessment of the externalized cost, imposed on the neighbor. The second step is a finding of guilt and the infliction of punishment. For example, section 9(1)(e) of the Victorian Summary Offences Act 1966 provides for a fine of \$3,500 or up to 6 months imprisonment for criminal trespass. In the absence of punishment, the rest of society would not be compensated for the costs imposed on it. Those social costs include apprehension, distrust of others, and excessive expenditure on self-protection. The deterrence that follows punishment, as well as being an externalized benefit or positive externality, is a public good, because everyone in society is able to consume it simultaneously and no one can be excluded on the basis of willingness and ability to pay. Punitive or exemplary damages would be an imperfect substitute for punishment, even though it is unlikely that they could be insured against, because as already noted, the ability of the injurer to pay can substantially impact their deterrence value. This is particularly the case in countries such as Australia where a defendant cannot

be punished twice by an award of punitive damages and criminal conviction (Mendelson 2010, p. 48).

Legal negligence provides the background for the second example. Mendelson writes: "the advent of railways in the early 1830s, which brought in its wake an unprecedented toll of accidental injuries and death, provided the impetus for the development of negligence as a separate tort" (Mendelson 2010, p. 277). The entitlement not to be injured or killed by negligent driving is one of the rights recognized and protected by this tort and the criminal law. Protecting road and street users' rights not to be interfered with by negligent driving using the market mechanism or Coase bargains would entail very high transaction costs and thus market failure (Coase 1937, 1960). Drivers would have to locate and then contact every potential victim of their negligent driving and then negotiate a price at which each victim would be prepared to relinquish the right not to be negligently harmed. Alternatively, every potential victim would have to locate and contact every potential negligent driver, and then negotiate the price to buy the right not to be harmed. For both injurer and victim, it would not be economical to use cars, streets, or the roads because the search and bargaining costs, (transaction costs) would be too high (Posner 2010). In this case however, unlike the first where the property owner is compelled to bargain with his neighbor if he does not want his view to be obstructed, transaction costs are too high to justify a market solution.

Legal negligence requires the victim to establish that the injurer breached a legally recognized duty of care, which factually causes reasonably foreseeable damage (Mendelson 2010, p. 281). Similar elements constitute the criminal counterpart of the tort of negligent driving. For example, S.318(2)(b) of the Victorian Crimes Act 1958 provides that:

Any person who by the culpable driving of a motor vehicle causes the death of another person shall be guilty of an indictable offence and shall be liable to level 3 imprisonment (20 years maximum) or a level 3 fine or both. For the purposes of subsection (1) a person drives a motor vehicle culpably if he drives the motor vehicle negligently, that is to say, if he fails unjustifiably and to a gross degree to

observe the standard of care which a reasonable man would have observed in all the circumstances of the case.

In both of these examples, the cause of the externalized cost problem is not an absence of property rights, since these are well defined in both cases. The respective sources of the problem are market bypass where a market transaction would have been relatively cheap and failure to observe a legal standard of care in the face of prohibitively high transaction costs that make market bypass impossible (Posner 2010).

Judicial Valuation of Externalities

The notion of “price lists” for externalized harms can be found very early on in the history of Anglo-Saxon and Germanic law. An example is “the code of Æthelberht, the King of Wessex, which contains elaborate tariffs of fines for breach of the peace” (Mendelson 2010, p. 10). More generally, “wergeld” tables served two functions. First, they provided for a fixed scale of compensation, which was determined by the victim’s social and legal status. For example, the “wergeld” of princes and free lords was 360 shillings, the judicial class 30 shillings, rent-paying tenants and other free-men 15 shillings, and a day laborer’s “wergeld” was paid in wheat (Mendelson 2010, p. 34). Second, the tables put a monetary value on injuries to different parts of the body, which was proportional to the victim’s “wergeld”; for example, the price of permanent injury to the mouth, nose, eyes, tongue, ears, male sexual organs, hands, and feet was set equal to one half of the victim’s “wergeld” (Mendelson 2010, p. 35).

In contemporary times judicial valuations of externalized costs can be inferred from the average quantum of compensation they award in torts to victims and the average quantum of punishment they impose on offenders. The averages aggregate and summarize the dispersed or localized information about the distribution of diverse cases for a particular cause of action and offense. They are socially optimal because the judges’ comparative advantage is in producing justice according to

law. This requires access to all of the relevant information about the case, and knowledge of the relevant substantive law, which they only possess. The last statement needs to be somewhat qualified when considering the ‘optimality’ of court awarded tortious damages. In Australia, following reform legislation early this century, a distinction is now made between intentional and unintentional wrongs; the former are still governed by the common law of damages, while the latter are governed by statute (Mendelson 2010). Statutory based damages are subject to statutory thresholds and capping (Mendelson 2010). Consequently, judicially determined awards in the case of negligence for example, are constrained optima. However common law principles also considerably constrain the courts’ assessment of the victim’s disability. In estimating ‘the quantum of damages for past and future pain and suffering, loss of enjoyment of life and loss of earning capacity’ courts apply the ‘once for all’ rule established in 1699 (Mendelson 2010). Compensation is a lump sum, which cannot be subsequently changed, if the plaintiff’s injury worsens or develops into something more serious down the track (Mendelson, 2010). Similarly, when victims sustain very serious and permanent injuries, for example quadriplegia, courts face insuperable obstacles in forecasting the victim’s future loss of earning capacity and nursing requirements. As noted by Mendelson (2010), this situation makes it very likely that the gravity of the victim’s injury and injurer advantage are positively correlated. Average damages denoted by AD measure the price of the externalized harm borne by the victim. The supply of absolute general deterrence plus the judicial valuation of the externalized cost to society implied by the optimal punishment is found by minimizing Eqs. 1 and 2 with respect to X^* and F^* , the optimal jail sentence and fine, respectively:

$$\begin{aligned} \text{MIN.E}[C] &= E[D[O[X^*]]] + P X^* b O[X^*] \\ &= D[O[X^*]] + E P X^* b O[X^*] \end{aligned} \quad (1)$$

$$\begin{aligned} \text{MIN.E}[C] &= E[D[O[F^*]]] + P F^* O[F^*] \\ &= D[O[F^*]] + E P F^* O[F^*] \end{aligned} \quad (2)$$

where $E[C]$ is expected cost, D is harm, O is offenses, EP is the expected probability of the offender being jailed or fined, b is the cost of incarcerating an offender each time period, and X^* and F^* are the average jail sentence and fine for the offense. The asterisk indicates that they are exogenous and optimal in the sense explained earlier. The solutions are given by Eqs. 3 and 4, respectively:

$$\frac{F^*EP}{e} + F^*EP \quad (3)$$

$$\frac{X^*b^*EP}{e} + X^*b^*EP \quad (4)$$

The first term on the RHS of Eqs. 3 and 4 is the value of the positive externality corresponding to the optimal fine F^* and term of imprisonment X^* , given EP the probability of the sanction being imposed and e the absolute general deterrence elasticity, whose value will lie between 0 and -1 . A value of -0.5 , for example, indicates that a 1% (10%) increase in the average fine or jail sentence lowers the expected future costs of crime by 0.5% (5%), etc. A value of -1 indicates perfect absolute general deterrence. The second term of Eqs. 3 and 4 is the court's valuation of the externalized social cost of the offense, i.e., the burden placed on wider society:

$$V_N = AD + F^*EP \quad (5)$$

$$V_N = AD + X^*b^*EP \quad (6)$$

Expressions 5 and 6 give the dollar value (V_N) of the court's valuation of the negative externality implicit in the award of tortious damages (AD) and the punishment imposed for the corresponding offense, while Eqs. 7 and 8 give the value of the positive externality (V_P) from deterrence:

$$V_P = \frac{F^*EP}{e} \quad (7)$$

$$V_P = \frac{X^*b^*EP}{e} \quad (8)$$

The two cases discussed in the third section of this essay can be used to illustrate how these

expressions would be translated into dollar values. The parameter values used are deterrence elasticity -0.3 , the probability of a fine or imprisonment 0.5 , and the annual cost of incarceration $\$80,000$.

Case 1

	Damages	Fine (average value)	Imprisonment
Tort of trespass to land	\$5,000		
Offense of trespass to land		\$5,000	6 months
Judicial value of negative externality			
(i) Damages + fine		\$7,500	
(ii) Damages + imprisonment			\$15,000
Judicial value of positive externality			
(i) Fine		\$8,333	
(ii) Imprisonment			\$33,333
Total: negative and positive externality		\$15,833	\$48,333
Civil output	\$5,000		
Criminal output		\$10,833	\$53,333
(Assumes only 1 case: civil and corresponding criminal matter)			

Case 2

	Damages	Fine (average value)	Imprisonment
Tort of negligence	\$20,000		
Offense of culpable driving		\$20,000	1 year
Judicial value of negative externality			
(i) Damages + fine		\$30,000	
(ii) Damages + imprisonment			\$60,000
Judicial value of positive externality			
(i) Fine		\$33,333	
(ii) Imprisonment			\$133,333
Total: negative and positive externality		\$63,333	\$193,333
Civil output	\$20,000		
Criminal output		\$43,333	\$173,333
(Assumes only 1 case: civil and corresponding criminal matter)			

Summary

The production of goods and services that are sold in the marketplace increases social welfare because it generates a social surplus, profit plus consumer surplus. The latter is the difference between the average prices paid for an item and buyers' maximum willingness to pay and is a measure of consumer welfare. Profit measures business surplus, which is the difference between revenue and the opportunity cost of all scarce resources used to generate it. Conceptually

valuing the output of products that are priced in the market is straightforward. This is not the case however for nonprofit services that are not priced by the market mechanism.

Final output valuation in these cases requires a well-developed theory of the organization's economic functions. In relation to the courts, the position adopted in this essay is that they price external effects in missing markets, in both the civil and criminal jurisdictions. The valuation of their final output follows logically from this. Average civil and criminal jurisdiction output is equal to expressions $5 + 7$, where fines are used as punishment, and expressions $6 + 8$, where imprisonment is used. Total civil jurisdiction output is average damages multiplied by the number of cases (the first term in Eqs. 5 and 6), and total criminal jurisdiction output is the second terms of Eqs. 5 and 6 plus Eqs. 7 and 8 multiplied by the number of cases.

As the two examples show, the pricing exercise is related to the sanction used; the negative externality of land trespass is judicially valued at \$7,500 (damages + fine) and \$15,000 (damages + imprisonment), while the corresponding figures for negligent driving are \$30,000 and \$60,000, respectively. The value of the positive externality or public good of deterrence is \$8,333 (fine), \$33,333 (imprisonment) for land trespass, and \$33,333 and \$133,333 for negligent driving.

Fiduciary Duties

Remus Valsan
Edinburgh Law School, University of Edinburgh,
Edinburgh, Scotland, UK

Definition

Fiduciary duties arise in legal relations where one party, the fiduciary, acquires decision-making authority over the interests of another party, the beneficiary. The first party becomes bound by a set of duties aimed at ensuring that he exercises his discretion in the best interests of the beneficiary, to the exclusion of his own interests or the interests of third parties. Fiduciary duties are strictly enforced by the courts, in order to ensure a proper exercise of discretion by the fiduciary and to preserve the utility of fiduciary relations.

Fiduciary Relations

Fiduciary duties arise in fiduciary relations. Fiduciary relations exist in multiple forms in different legal areas, such as private law, commercial and corporate law, family law, and, in some cases, public law. The concept of fiduciary duties is sometimes regarded as a purely common law concept, historically intertwined with the institution of trust and with the equitable jurisdiction of the English Court of Chancery (Sealy 1962). Looking at the substance, rather than the history or technical details of fiduciary relations, however, reveals that such relations exist across all legal traditions. The common law and mixed jurisdictions have developed an elaborate set of principles which constitute a body of fiduciary law. In civil law countries, in contrast, fiduciary relations have developed in a more isolated and fragmentary manner (Graziadei 2014). For this reason, most of the relevant theoretical literature comes from common law or mixed jurisdiction authors. Because the underlying features and issues are similar in all fiduciary relations, many of the insights discussed below are not jurisdiction specific.

It is commonly stated that the family of fiduciary relations is open ended. It comprises established (or *per se*) fiduciary relations and *ad hoc* fiduciary relations. Examples of established relations include trustee-beneficiary, agent-principal, tutor-ward, director-company, or solicitor-client. In some jurisdictions, especially Canada and the USA, the list of

established categories is longer: it includes relations such as physician-patient, clergy-parishioner, parent-child, or Crown-aboriginal peoples. Fiduciary duties may also arise *ad hoc* in legal relations that do not belong to an established category, based on the concrete factual circumstances. In the *per se* fiduciary relations, fiduciary duties are presumed to exist (rebuttable presumption), whereas in the *ad hoc* relations, the existence of fiduciary duties must be proved, based on relevant indicia (Shepherd 1981).

The recognition of the open ended nature of the family of fiduciary relations has created the need to identify the core indicia or elements that trigger the application of fiduciary duties in new circumstances. Beyond the general consensus concerning the two types of scenarios where fiduciary duties may arise, courts and theorists have expressed many different views with respect to the necessary and sufficient core elements that attract fiduciary duties. Two elements are increasingly recognized as indispensable for fiduciary duties to exist: an undertaking to act for the interests of another coupled with power or discretion to affect the other's legal or practical interests (Valsan 2016).

The requirement of undertaking to act for another signifies that fiduciary duties are triggered voluntarily. They are enforceable only against those persons who undertook to do something for the benefit of another person or for an abstract purpose. This means that fiduciary duties cannot be imposed by courts *ex post* in an instrumental way, in order to achieve a certain outcome or trigger a desirable legal remedy, if there is no undertaking from the fiduciary to act in the beneficiary's interests. Furthermore, the fiduciary undertaking to act in the interests of another is not a duty to achieve a certain result, *i.e.*, a binding obligation to achieve the best result available for the beneficiary. Such an obligation would minimize or remove the role of discretion and would render the fiduciary office very cumbersome. Moreover, it is established that courts will not second-guess a fiduciary's judgment *ex post*, based on the results achieved. This rule, known in the company laws of certain jurisdictions, such as Delaware, as the business judgment rule,

protects fiduciaries that exercise their judgment in good faith, with due care and without conflicts of interest, from liability based on the results of their decisions (Valsan and Yahya 2007). The requirement of power, or decision-making authority involving exercise of judgment, indicates that fiduciary duties are imposed only when a party has scope to exercise discretion over the interests of another (Thomas and Hudson 2010). In contrast, when a contractual party has an obligation to act in the other party's interest in a clearly prescribed manner or following the other party's directions, contractual, rather than fiduciary liability, will normally arise.

Fiduciary Duties

When a party undertakes to act in the interests of another and acquires decision-making authority with regard to how to pursue the other party's interests, fiduciary duties are imposed in order to ensure the integrity of the exercise of discretion. Which duties are properly regarded as fiduciary is a matter of some controversy. All authors agree that the proscriptive (negative) duties forbidding fiduciaries to act in a conflict of interest or to seek unauthorized benefits are fiduciary duties. Some authors add to these proscriptive duties a set of positive (or prescriptive) duties, such as a duty to act in good faith, a duty of reasonable care and diligence, a duty to disclose relevant information, or a duty not to disclose confidential information (Finn 1977). The fiduciary status of these positive duties is disputed. The preferable view is that, although duties of good faith, care, confidentiality, or disclosure are often associated with a fiduciary position, they apply to a wide spectrum of non-fiduciary legal actors as well and therefore should not be labeled fiduciary (Conaglen 2010).

The proscriptive fiduciary duties are commonly expressed as four fiduciary rules: the no-profit rule, the no-conflict rule, the self-dealing rule, and the fair dealing rule. The no-profit rule forbids a fiduciary from retaining an unauthorized benefit acquired by virtue of his fiduciary position. The no-conflict rule states that a fiduciary is not allowed to place himself in a position where

his personal interest, or interest in another fiduciary capacity, conflicts or possibly may conflict with his duty. The self-dealing rule renders voidable, at the beneficiary's will, purchases by a fiduciary, in his personal capacity, of property under his administration, irrespective of the honesty of the transaction. The fair dealing rule renders voidable the purchase by a fiduciary of the beneficiary's interest, unless the fiduciary demonstrates that the transaction is entirely fair and honest and that the beneficiary gave his informed consent (Smith 2003).

A defining feature of the proscriptive fiduciary duties is their particular strictness. The degree of strictness varies with the type of fiduciary relation and jurisdiction. For instance, fiduciary duties of trustees are generally more demanding than those of company directors, and US courts are more permissive than UK courts when it comes to self-dealing by directors (Kershaw 2012). Notwithstanding these differences, fiduciary duties are often regarded as stricter than other private law obligations. One manifestation of this strictness is the reprehensibility of the appearance of self-interested conduct. A fiduciary will be liable for breach of the no-conflict rule not only in case of an actual conflict between interest and duty but also when he acts in a situation of potential conflict of interest. A potential conflict arises when there is a real sensible possibility of conflict, and the fiduciary is liable if he acts in these circumstances irrespective of his good faith or proper motivation. Moreover, when the proscriptive duties are breached, a fiduciary is generally liable irrespective of whether the beneficiary suffered any loss or even obtained a benefit following the conflicted transaction. Furthermore, a fiduciary is forbidden from taking a business opportunity he came across while exercising his role, even if the opportunity is not available to the beneficiary (Conaglen 2010).

Remedies for Breach of Fiduciary Duties

Breach of fiduciary duties attracts personal and proprietary remedies. Some remedies are aimed to recover the profits that the fiduciary obtained

through breach of fiduciary duty. They focus on undoing the wrong rather than on compensating the beneficiary for his loss. Disgorgement of profits may be sought under a personal claim in the form of account of profits, or under a proprietary claim, in the forms of constructive trust or equitable lien. Other remedies aim to compensate the beneficiary for his loss: the equitable compensation or damages. Another potential remedy, applied more rarely and when the breach was in bad faith, is the imposition of exemplary (or punitive) damages, over and above disgorgement of profits, or compensation for loss. Furthermore, a transaction entered into in breach of fiduciary duty is voidable at the instance of the beneficiary. This remedy usually leads to rescission, where the transaction is unwound and the parties are restored to their previous positions (McGhee et al. 2015).

These remedies could be generous to beneficiaries and therefore are extremely attractive. The beneficiary may bring a claim for disgorgement of profits without the need to prove loss; a proprietary claim will shelter the beneficiary against the consequences of fiduciary's insolvency; a claimant can seek compensation for loss without being restrained, in form at least, by the common law rules of causation, remoteness of damage, or contributory negligence. The desire to have access to these remedies is one of the reasons why claims for breach of fiduciary duty are very popular (Millet 1998).

When an actual or potential breach occurs, a fiduciary has the option to escape liability by fully disclosing the relevant information (e.g., the actual or potential conflict of interest or the benefit that was not authorized *ex ante* by the relationship) to all relevant beneficiaries and seek their informed consent.

The Purpose of Fiduciary Duties

Fiduciary Duties as Gap Fillers

In a view that dominates the law and economics literature in this area, the purpose of fiduciary duties is to fill in the gaps in the fiduciary contract. Because the fiduciary relation engenders

unusually high costs of specification and monitoring, parties specify *ex ante* a generic duty of loyalty (the fiduciary's duty to act in the best interests of the beneficiary), and courts spell it out *ex post* by identifying what the parties would have agreed on if they had written a fully specified contract (Easterbrook and Fischel 1996).

The gap filling approach, also known as the contractarian theory of fiduciary duties, dominates the current law and economics fiduciary theory. Fiduciary relations are regarded as a particular type of contract, one that is characterized by large gaps in the parties' agreement (Cooter and Freedman 1991). Although most contracts are incomplete, fiduciary relations have a particularly high degree of incompleteness. There are two main causes for this. First, parties to a fiduciary contract seldom label their relation as fiduciary, rarely include terms from the standard fiduciary vocabulary, such as loyalty or unselfishness; and seldom bargain *ex ante* over all circumstances that may constitute a conflict of interest or an unauthorized benefit (Duggan 2010). Second, at a more fundamental level, the high incompleteness of the fiduciary contract is due to its essential feature: the beneficiary (the principal) hires an expert fiduciary (the agent) and entrusts him with management and control of an asset or with another task involving exercise of discretion. The agent acquires an open-ended power over the asset and undertakes imperfectly observable discretionary actions that affect the principal's wealth. Because the agent's expertise and professional judgment are a key justification for the creation of the fiduciary relation, the principal has neither the ability nor the incentive exhaustively to specify *ex ante* what the agent should do (Jensen and Meckling 1976).

Fiduciary duties are, thus, a tool used to fill in the contractual gaps in the fiduciary contract. The completion of the fiduciary contract is often delegated to courts. Courts supply the missing contractual provisions by identifying the terms the parties themselves would have agreed to, had they negotiated about the unanticipated circumstance *ex ante* (Alces 2015). In the contractarian approach, fiduciary duties are mere standard terms in contracts, derived and enforced in the same way

as other contractual undertakings. The implications of this approach are manifold. First, contractarians deny that fiduciary duties serve a moral or public interest function. They have the same objective as contractual obligations in general, namely, to implement the parties' own perception of their joint welfare (Easterbrook and Fischel 1996). Second, the court's role in enforcing a fiduciary contract is limited to supplying default rules that parties are free to contract around *ex ante*. Parties who are able to determine *ex ante* that they do not want fiduciary duties to apply to certain aspects of their bargain are free to exclude such circumstances either generally or on a case-by-case basis, via an obligation of *ex ante* disclosure and informed consent. Consequently, the fundamentally contractual nature of fiduciary duties means that courts cannot override express or implied contractual terms in furtherance of other, higher-ranking, interests. When economic agents enjoy complete freedom and autonomy to decide the form and content of their bargains, they engage in wealth-maximizing exchanges that promote economic efficiency (Duggan 2010).

Fiduciary Duties as a Tool to Protect Relations of Trust and Confidence

Another view, sometimes referred as the anti-contractarian approach to fiduciary duties, is based on the idea that fiduciary relations have a special nature compared to regular private or commercial interactions. They are marked by a high degree of trust and confidence that one party places in the other, which causes the former to be particularly vulnerable to abuse of power by the latter (Flannigan 1989). Once the beneficiary relinquishes control over the entrusted asset or task, the fiduciary is presented with opportunities to misappropriate the asset or opportunities arising in relation to its management, whether by theft, conversion, self-dealing, or negligence (Frankel 1995). The idea of vulnerability to abuse is sometimes conveyed using the concept of fiduciary expectation. The most important indicator of a fiduciary relation is the fiduciary expectation, which entitles one party to expect that the other will act in the first party's interests for the purpose of the relationship to the exclusion

of his own personal interests. Due to this expectation, the trusting party relaxes his self-vigilance and independent judgment and becomes vulnerable to abuse. Consequently, in this view, courts impose *ex post* fiduciary duties not as an approximation of what parties would have agreed to, but in order to protect vulnerable people in power-dependency relationships (Finn 1989).

In the anti-contractarian view, fiduciary duties are an instrument of public policy used to maintain the integrity, credibility, and utility of relationships perceived to be of importance in society. Because such unequal power-dependency relations are pervasive and particularly valuable for the society, they have moral and public interest dimensions not captured by the contract law framework. Due to these specific dimensions, in certain cases fiduciary duties trump the individual interests of the parties.

Fiduciary relations and regular contractual relations are viewed as fundamentally different. In contract parties are usually on equal footing and expected to further their own interest, within the limits of good faith, unconscionability, and undue influence. Fiduciary relations, in contrast, have trust and confidence, vulnerability, and dependency of one party on another, at their core. The underlying rationale of the fiduciary obligation is not individualistic private ordering. The law in this area serves an educative or pedagogic function, aiming to heighten the morality of the marketplace by raising the standards of commercial dealings above ordinary market temptations.

Fiduciary Duties as a Tool to Protect the Exercise of Fiduciary Discretion

This view of fiduciary duties links the proscriptive fiduciary duties with the essential characteristic of a fiduciary relation, the decision-making authority over the interests of another. The content and purpose of duties specific to persons in a fiduciary position are easier to grasp if these duties are separated into two main groups. On the one hand, there are the traditional proscriptive fiduciary duties, usually articulated as the no-conflict and no-profit rules. On the other hand, there is a core duty binding on fiduciaries, which is different from the proscriptive duties and which justifies

their existence. The proscriptive duties are connected with the core duty in the sense that they play a protective or prophylactic role: they aim to prevent violations of the fundamental fiduciary duty. The core duty binding on a fiduciary is the duty to exercise discretion based on relevant considerations (Valsan 2016).

In general terms, a fiduciary is bound to exercise discretion within the objective limits of his powers and in what he believes to be the best interest of the beneficiary or the scope for which the power was granted. The determination of beneficiaries' best interests or of the purposes for which a power was granted allows the fiduciary a large degree of subjectivity, within a clearly defined legal perimeter. An appropriate exercise of discretion imposes on fiduciaries two requirements. First, a fiduciary must exercise active discretion, in the sense of applying his mind and reaching a conscious decision regarding the need for, and the implications of, exercising any power or discretion that he holds in fiduciary capacity. Second, if a fiduciary decides that it is opportune to exercise a power, he must decide where the best interests of the beneficiary lie, or what is the best way to achieve the purpose for which the power was given, depending on the type of power under exercise. The two aspects of the exercise of judgment involve a similar decision-making process: fiduciaries must decide based on relevant considerations (Thomas 2013).

The proper judgment duty has a procedural nature. It tells a fiduciary what to do when exercising discretion, rather than what is a relevant consideration for each decision. Determining the considerations that are relevant to an exercise of discretion is a matter for the fiduciary's judgment. Such considerations include the nature and the purpose of the particular power to be exercised; the relationship that the power has to the other powers and duties of the fiduciary; the nature of the transaction in which the fiduciary intends to perform; the wishes, circumstances, and needs of beneficiaries; fiscal considerations; and so on. The weight that each of these relevant factors should carry in determining the course of action is also a matter left to fiduciary's judgment. As long as fiduciaries apply their mind to the importance of

a relevant consideration for a particular decision, they comply with the duty of real and genuine consideration of relevant factors, irrespective of the actual outcome of their decision (Thomas 2013).

The proscriptive fiduciary duties protect the core duty to exercise judgment based on relevant considerations in two ways. First, they compel a fiduciary consciously to eliminate self-interest or the interest of a third party not relevant to the fiduciary relation from the list of considerations that a fiduciary is allowed to take into account when exercising judgment. Secondly, they protect the exercise of judgment against any potential indirect or nonconscious effect that the presence of an irrelevant interest may have on fiduciary's judgment. The mere presence of an actual or potential intruding interest affects the reliability of fiduciary's judgment in ways that cannot be measured and corrected against. Extraneous interests have the potential to affect the way in which the decision-maker evaluates the seriousness of various risks, the desirability of certain outcomes, or the perception of connections between cause and effect (Davis 2012). Conflict of interest situations are reprehensible because they create an unusual risk of error, thus rendering one's judgment less reliable (Norman and Macdonald 2010). Since the effects of an extraneous interest cannot be accurately measured, the reprehensibility of a fiduciary conflict of interest does not depend on the fiduciary's good faith or genuine desire to act solely in the beneficiary's best interests. A fiduciary is in breach of the no-conflict rule on the basis of being in a conflict situation, irrespective of his belief that he is capable of resisting the temptation or corrupting influence of the interest that could interfere with his judgment.

Conclusion

Fiduciary duties are obligations binding on persons occupying fiduciary positions, which compel such persons to refrain from adopting decisions in circumstances that may amount to conflict of interest, unauthorized benefits, self-dealing, or unfair dealing with the beneficiary. They guide

and protect the exercise of the fiduciary's decision-making authority by removing the actual or potential influence on fiduciary's discretion of factors or interests that are not relevant to the scope of fiduciary's authority. Fiduciary duties have been regarded as an efficient method to fill in the large gaps in fiduciary contracts by postponing or delegating to courts the specification of the actions that a fiduciary is allowed or prohibited in his mandate to promote the interests of the beneficiary. Because courts tend to have a strict approach to fiduciary's liability, fiduciary duties have also been regarded as a public policy tool that protects valuable social relations characterized by trust, confidence, power, and dependency.

Financial Education

Marco Novarese¹ and Viviana Di Giovinazzo²

¹Department of Law and Economics, University of Eastern Piedmont, Centre for Cognitive Economics, Alessandria, Italy

²Department of Sociology and Social Research, University of Milano Bicocca, Milan, Italy

Definition

Financial education is an area of research involving finance, psychology, and behavioral and cognitive economics that grew out of the need to improve the financial skills of citizens. It aims to promote consumer awareness concerning the functioning of financial markets through financial training and continuing education which help to develop the skills and knowledge that allow

individuals to make informed, effective decisions concerning their financial resources.

Historical Outline

Financial education was introduced into a number of American secondary schools from the late 1950s onward, with the aim of providing citizens with basic financial knowledge on incomes and savings, taxation, first home buying, insurance, and pensions. During the 1960s, reinforced by the Johnson Great Society Program and Ralph Nader's consumer protection campaigning, financial education programs multiplied and even became compulsory in some states. By the 1990s there was a growing awareness of the need for financial education, with citizens facing a rapid increase in the supply of products and financial services.

In 1995, the US Department of Labor and the Treasury, as well as 65 public and private organizations, organized the first American Savings Education Council. Surveys investigating household financial decision-making have been regularly conducted since 1997, especially by the Jump\$tart Coalition for Personal Financial Literacy. In 1998, the Securities and Exchange Commission set up the Facts on Savings and Investing Campaign. Its initial report states that "One of [financial education's] major goals is that all Americans are armed with the information they need to make sound financial decisions and protect their hard-earned savings" (SEC 1999). Most surveys report a progressive worsening in financial matters.

From the data it emerges, for example, that the average family debt with credit card companies rose from an average of \$2,985 in 1990 to an average of \$8,300 in 2002 (Fisher 2003). Other data indicate that in 2001, the average American saved 1.6% of his disposable income, compared to an aggregate personal saving rate of 7% in the period 1959/2001 (US Bureau of Economic Analysis 2002). In 2003, the share of households that declared bankruptcy reached an estimated record of 1.5% (Boushey and Weller 2006). The data report, furthermore, a high number of

individuals still not availing of banking services (Hilgert et al. 2003). Some research also shows that the higher the citizens' level of financial knowledge, the greater their likelihood of acquiring financial products and services as well as making more informed saving and investment choices. Various initiatives have therefore been undertaken to promote the financial inclusion of the poorer sections of the population in order to increase their autonomy.

Since the early 2000s, and particularly after the 2008 financial crisis, governments and financial institutions have insistently highlighted the need for financial education as a matter of first priority, partly with the aim of instilling new trust in markets and financial products. The literature, however, reveals contrasting opinions on the efficacy of the programs. Some studies do not find a direct link between financial education and changes in investment decision-making (Choi et al. 2004; Cronqvist and Thaler 2004). Others, such as Bernheim et al. (2001), identify a direct connection between financial education, higher saving rates, and higher net worth in states with compulsory financial education courses. Other studies suggest that counselling sessions can contribute to reducing the risk of delinquency. In a study carried out on health and retirement, Lusardi (2004) observes that attending seminars is also associated with an increase of both financial and total net worth.

Aims of Financial Education

According to experts like Lusardi and Mitchell (2007, 2011, 2014), the main aim of financial education is to make citizens become more rational economic agents – an essential condition for efficient markets – and also more autonomous in making decisions on purchases. They feel, therefore, that the general deterioration in the financial position of savers has been caused in the first place by the rapid circulation of financial products of greater complexity (e.g., credit cards, revolving credits, subprimes, student loans, payday loans, and tax refund loans), which, thanks to the technological progress (like home banking), have also reached small investors directly, making them

more vulnerable to predatory loans. In the second place, there is an even lower level of familiarity with financial matters, due in part to limited knowledge of mathematics.

Studies testing mathematical/financial skills have, in fact, revealed serious inadequacies in three areas of great importance: compound interest, inflation, and stock risk. Lusardi and Tufano, for example, surveyed 1,000 US residents and found that 36% of the respondents were able to do a compound interest calculation, 35% understood that making minimum credit card payments means essentially never paying the balance off, and only 7% understood that making a \$1,200 payment at the end of a year is more advantageous than making monthly payments of \$100. Similar surveys report that Europeans also need support to understand and make effective use of certain financial products.

In the European countries taking part in the OECD/INFE survey (International Network on Financial Education 2016), with the exception of Estonia, the Netherlands, and Norway, (where between 76% and 80% of the population answered correctly), the calculation of simple interest on savings posed a problem for at least 25% of respondents, rising to over 50% of the population in Albania and the Russian Federation. With respect to compound interest, the large majority of Europeans are unable to understand that the value of interest following 5 years' compounding is more than five times the simple interest. Again, the Netherlands and Norway stand out as exceptions. The concept of risk diversification appears to be even more challenging: over 30% of the population do not understand what it is, in Albania, Austria, Belgium, Croatia, Czech Republic, Estonia, Hungary, Latvia, the Netherlands, Norway, Poland, the Russian Federation, and the United Kingdom.

Cognitive and Behavioral Critique

The data also show that financial education can have the side effect of increasing the citizens' faith in their own financial abilities, even though no improvement has actually been made. Forty percent of the FINRA respondents declared they had

high or very high levels of financial knowledge, despite the fact they were proven to be limited (Lusardi and Tufano 2009). In a survey carried out in Australia, 67% of the respondents declared they knew what compound interest was, but only 28% were able to give the correct answer to a question on the subject (OECD 2006).

Behavioral researchers (i.e., Bernartzi and Thaler 2004) have investigated the possibility that increased financial knowledge has a positive effect on intended behavioral changes but without necessarily bringing them about. Choi et al. (2004) report that 35% of contributors interviewed about pre-retirement saving plans 401(k) declared they intended to make greater savings in the future. In the following 4 months, however, the majority (86%) had not made any changes in their personal saving habits. In a similar way, Clark et al. (2006) show a very weak correlation between good intentions and actual changes in saving habits, presumably caused by the intervention of psychological variables such as the peer effect. In contemporary consumer society, limited interest in savings may be caused by the pressures of conspicuous consumption.

Cognitive and behavioral economists find it useful to study the problems connected to financial education in the context of bounded rationality (Simon 1978) and cognitive bias (Tversky and Kahneman 1981, 1991; Elster 1996; Frederick et al. 2002; Gigerenzer 2007). In contrast with conventional, neoclassical theory, which attributes full rationality to the individual, behavioral finance holds that, given the available alternatives, people are unable to make the optimal choice. This occurs for multiple reasons, including asymmetric information and the fact that the rationality of decisional processes is altered by heuristic-induced, systematic computational errors (i.e., mental shortcuts adopted when faced with the excessive complexity of calculation), as well as personality (risk aversion, tendency to procrastinate) and emotive factors (anxiety, indecision, fear, euphoria).

Such factors are classified by the literature as problems of self-control, e.g., the tendency to overborrow/under-save, procrastinate, and/or manifest overconfidence. Other psychological

phenomena include hyperbolic discounting (e.g., preferring \$10 today to \$12 in a week's time but preferring \$12 in a year and a week to \$10 in a year), herding (imitating the decisions of others as a form of mental shortcut, whether based on the supposition that others know more or simply in order to conform), loss aversion, status quo bias (showing a preference for the status quo even when it does not increase material well-being), the framing effect (when a decision is influenced by the way various options are presented), anchoring (the tendency to base choices on reference points, such as peer advice, which is not objectively relevant), and nonstandard probabilistic thinking (e.g., lottery purchases).

Behavioral economists also show that financial education programs with a good content can fail because of the way in which they are structured or presented. For example, research has shown that women have different preferences for investments and respond differently to choice framing (Croson and Gneezy 2009). To be pigeonholed as poor can make those on low incomes reject a course and refuse to follow it (Ross and Nisbett 2011). Similarly, the elderly have different requirements and different attitudes toward phenomena like risk and uncertainty (Agarwal et al. 2009).

There are, indeed, deep-seated problems inherent in financial education. Firstly, research reveals persistent weaknesses in basic mathematical/financial knowledge. Secondly, it indicates the presence of systematic errors which affect decision-making processes and serve to limit rationality. Lastly, the efficacy of financial education depends largely on how the programs and courses are presented and the kind of clientele they target.

Given the widespread limited knowledge of mathematics, the OECD created in 2012 the Programme for International Student Assessment (PISA), the first large-scale international study, which examines the financial knowledge and competence acquired by 15-year-olds both within and outside school. From the 13 OCSE countries taking part in the initial enquiry, it emerged that only 10% of the students could analyze complex products and solve financial problems of above-average difficulty. The PISA enquiry also highlights the fact that an average student with a more

advantaged socioeconomic profile tends to score a higher mark than one from a poorer background. Such data appear to confirm the importance of financial inclusion as a means of reducing social inequality.

Research on psychological traps and systematic errors – Thaler and Sunstein (2008) – indicates the need for experts, such as brokers and financial advisors, to help citizens to make informed choices. To solve the problems of asymmetric information arising between citizens and experts, they deem it necessary to have policy-makers that safeguard individual choice with specific financial markets regulations, by indicating, for example, default options on mortgages, investment funds, and superannuation plans, which are not obligatory, but which become effective in cases of protracted indecision (i.e., libertarian paternalism).

Conclusion

Many of these problems involving financial education have led various researchers (Gale and Levine 2010; Willis 2011) to the conclusion that financial education is a necessary but ineffective instrument. The factors adduced are:

1. The complexity of financial decisions facing a saver who is not a professional investor.
2. The heterogeneity of consumer financial circumstances and values making it very difficult and expensive to form personalized plans.
3. The speed of change in product offerings and industry practices.
4. Individuals' lack of interest in taking part in programs that require a considerable investment of time and energy.
5. Persistent cognitive and behavioral biases in citizens who recognize the existence of psychological traps (Willis 2011: 429–430).

Finally, Willis highlights the high public costs of financial education programs and the fact that, paradoxically, they may actually limit individual autonomy. In order to keep up with the novelties and complexities of financial markets, compulsory lifelong learning would be required. Governments,

foundations, and international organizations thus need to weigh up the opportunity cost of financial education and remember that the limited efficacy of its programs often does not depend on factors related to the rationality of the individual citizen.

Financial Regulation

Hadar Yoana Jabotinsky
Faculty of Law, Hebrew University of Jerusalem,
Jerusalem, Israel

Abstract

Financial markets do have special attributes which require regulatory intervention. They are complex markets which are abundant

with asymmetric information, moral hazard, externalities, and agency problems. They are markets in which products mature over a long period of time causing a need for regulatory monitoring which is exacerbated by consumer demand for regulation and economies of scale in monitoring. Moreover, the financial firms in these markets are crucially important from a systemic point of view to the health of the economy in general. Having said all that, financial regulation is costly. Regulation in general should only be enacted if the costs of implementing it are lower than the benefits derived from what it seeks to achieve. Regulation is not about quantity but about quality. The “right” kind of regulation gives the financial institutions the incentives to act in a way which enhances social welfare and reduces market failures.

Introduction

Regulation tends to disrupt the market process and changes opportunities and costs for entrepreneurial discovery and profits. If a free market is generally a desirable goal from an economic point of view, why not allow it in the financial service sector? If nothing is wrong with the free market, then financial regulation becomes worthless or even harmful. If there is something wrong with it, with regard to the financial sector, then what is it exactly about the financial sector that makes the free market inefficient from an economic point of view? Assuming that the financial sector does require specific regulation, the second question that has to be considered is what are the costs of such regulation? If the costs exceed the benefits of regulating, then regulating is not desirable as it causes social welfare to decrease.

The following pages will attempt to put together a comprehensive list of the reasons for financial regulation and its potential costs. Some of the costs are not quantifiable, but may have a strong impact on the efficiency of the financial regulation; others are quantifiable and are used in the Regulatory Impact Analysis conducted by regulators before issuing a new piece of regulation.

The Building Blocks

What Are the Rationales Behind Regulation?

Traditional economic approach lists three main purposes behind regulating markets (Brunnermeier et al. 2009):

1. Insuring competition, constraining the use of monopoly power, and preventing distortions to the market's integrity
2. Protecting consumers in cases where asymmetric information, which is costly to obtain, might harm them
3. Protecting against externalities where the cost of regulation is lower than the costs of the externalities

This traditional approach to regulation is called **the public interest approach** which assumes that a market economy may produce undesirable outcomes to consumers. A different and more modern approach to regulation, **the self-interest approach**, claims that regulation is made to serve the interest of the regulated group. In other words, the group which stands to benefit and the group which stands to be harmed both have an incentive to influence regulation in order to produce a better outcome for them (Stigler 1971; Peltzman 1976).

These considerations come to play also in the financial markets. However, as the financial sector has a few special attributes which make it more prone for market failures and misuse of consumers, the considerations for regulating the financial market are slightly different than those which exist in markets in general.

When thinking of modern financial regulation, one can identify three main goals:

1. Preventing systemic risk
2. Protecting consumers/investors
3. Helping design a framework for deciding monetary policy and determining exchange rates

The economic rationale for regulation and supervision in banking and financial services has long been known and debated. Generally, the need for financial regulation stems from addressing the concerns and needs listed below (Llewellyn 1999):

- Internalizing externalities
- Reduction of transaction costs for an efficient allocation of financial resources
- Enhancing consumers and investors' confidence and reliance and preventing a race to the bottom of risk management criteria
- Limiting and preventing unwanted herding directions
- Fighting crime and terror (e.g., anti-money laundering regulation)
- Correcting market failures (e.g., information asymmetries and agency problems)
- Achieving economies of scale in monitoring and regulation
- Correcting behavioral biases on behalf of the consumers
- Responding to consumer demand for regulation
- Reducing litigation costs by referring consumer complaints to the financial regulator

These rationales can be divided into two general types of regulation and supervision: prudential regulation and conduct of business regulation.

Prudential regulation assumes that consumers do not have enough information to assess the stability of the institution in which they place their money nor are they in a position to assess its **risk approach** (Armour et al. 2016). In this case, regulation is needed to assure that the financial institution does not take on excessive risk and endanger consumers' savings. Even if consumers are given information at the time contracts are signed, it is not enough to protect them down the road from risky behavior on behalf of the financial firm. If systemic risk factors are taken into account, the need for prudential supervision is paramount. One of the most important roles of financial regulation is to prevent or minimize systemic risks, i.e., reduce externalities. Systemic risk is the risk that an entire system or market might collapse. This risk is exacerbated by links and interdependencies, where the failure of a single entity or cluster of entities can cause a cascading failure (Acemoglu et al. 2015; Committee on Capital Markets Regulation 2009).

Conduct of business regulation focuses on protecting consumers during their day-to-day encounters with financial firms. Such regulation will generally cover proper disclosure rules, fair

treatment of customers, and competence of advisors and other service providers. Generally speaking, conduct of business regulation solves problems arising from asymmetric information and principal-agent relationships and ensures proper conduct when doing business with consumers.

Why Not Use Contracts?

The economic literature considers contracts preferable to regulation, as regulation is generally costly and is likely to yield a less efficient allocation of resources than bargaining. As described by Llewellyn (1999) in the case of financial services, it is likely that contracts will fail. Contract failure has many dimensions, such as (i) agency conflicts which may lead to bad advice to consumers, (ii) insolvency of the supplying firm prior to the delivery of the goods, (iii) mismatch between the consumers' expectations and the product or service delivered, (iv) fraud on behalf of the financial institution, (v) incompetence to supply the product in the expected standard, (vi) misunderstanding of the type of product or of its risk attributes by the consumer, and (vii) behavioral inclinations which offset rational decision making by consumers. As explained above, financial markets are highly complex and are prone to asymmetric information and agency problems. For these reasons, contracts and law enforcement by market participants tend to not be enough to ensure a well-functioning market, and regulatory intervention is needed (Enriques and Hertig 2011).

The Rationales for Prudential Regulation

Prudential regulation can be divided into micro-prudential regulation which concerns itself with the stability of the individual institutions and macro-prudential regulation which is concerned with the stability of the financial system as a whole. In general, the rationale for prudential regulation stems from addressing the following major points:

Reducing Externalities

Unlike the "perfect" market described in the economic literature, financial markets do, when unsupervised, allow for externalities (for a

discussion on externalities and transaction costs in general, see Coase 1960). This is mainly due to the fact that a financial firm takes into consideration solely its own risk without taking into account the risks that society might suffer as a whole from its malfunction (Dodd 2002). The rationale behind regulating externalities is that the true price of the product is not reflected in the price (Baldwin et al. 2012). The results of such externalities became evident during the 2007–2009 financial crisis and the large "bail out" schemes which followed; financial institutions were at large not held responsible for the risks they undertook, and the society as a whole had to pay the price in order to avoid an even larger turmoil. Moreover, as some countries lacked some or all of this money, they had to increase their national debt, which might have negative effects on the economy of these countries in the future such as inflation or fluctuation of currency or reduction of their ability to lend more money if needed (Reinhart and Rogoff 2009). In 2007 – 2009 the excessive risk taking on the US market has spread to nearly all markets around the world affecting them and bringing down firms which, at first glance, did not have anything to do with the excessive risk taking in the US market.

The problem with systemic risk unfolded in financial firms is that even if the risk of collapsing is small, its consequences might be devastating. Even with capital restrictions on some financial institutions, such as banks, they may still produce some externalities as capital requirements may limit the amount of direct exposure to default, but indirect exposure is still prevalent. If capital requirements cannot prevent all externalities, could government guarantees such as deposit insurance reduce concerns with regard to risk-related externalities? The idea behind government guarantees is that consumers should not be forced to face the consequences of actions that were not under their control. However, in order for deposit insurance to protect against a run on the financial institution, the coverage of the insurance has to be 100%. This is not the current situation in most countries (Cecchetti 1999). The problem with the idea of granting insurance coverage for deposits is

that it induces moral hazard problems – banks might be tempted to take on more risks and to operate with less capital. Depositors on the other hand might seek banks who take on more risk as they can receive higher interest rates as long as the bank is solvent and still be compensated if the bank goes bankrupt. But if the deposit insurance is anything short of 100%, the incentive for a run on the bank in specific circumstances remains. The situation can therefore be viewed as a trade-off between preventing bank runs and preventing moral hazard problems. As deposit insurance removes the incentives of liability holders in the financial institution to oversight their financial institutions, there is a need for regulatory intervention which will guarantee that the behavior of the insured institutions is not irresponsible. In a way, financial regulation is expected to bring a cure to their inherent moral hazard problem.

Externalities are also present with regard to pricing of some securities, such as derivatives, OTCs (over the counters), and other securities which are based on an underlying asset. It is thought that the price of securities reflects the risk levels unfolded in the underlying asset. A more “risky” security, i.e., the one which yields more variance, will have a lower price. However, that is only true for direct ownership of the security. The risk unfolded in risky securities extends beyond direct ownership. That extra risk is not priced nor calculated within the price of such securities.

What is special to the type of externalities in the financial market is that they cannot be solved by self-regulation even if the financial institutions agreed to it, as the single financial institution itself is not aware of their magnitude.

Controlling Herding

Prudential regulation is also needed in order to prevent and limit unwanted herding directions. It is thought that investors influence other investors and this influence has a first-order effect (Devenow and Welch 1996). Herding is a concept which is hard to define, yet when we refer to herding in the financial sector context, we refer to it as decision making by entire populations which can lead to systemic erroneous, namely, suboptimal choices. Herding is the power behind

bubbles (for definition of the term, please see Garber 1990), bank runs, noise trading, and other unwanted phenomena in the financial markets which lead to distraction of wealth.

Bankers and other financial employees might also suffer from herding when comparing their actions to the actions of other financial employees in their sector and mimicking them. Thus, in times of crisis, there might be unwanted behaviors on behalf of financial employees (such as shortage of credit in the market due to the fact that one bank decides to cut down on its loans and all other banks react and follow).

Herding does not require coordination, but simply an ability to collect information about what others are doing in the market. There are two views with regard to herding; the first claims that investors/financial employees are not rational and simply behave like cattle in a herd, blindly following the lead of others. The second views investors/financial employees as rational players and puts its focus on externalities: optimal decision making is thought to be distorted by lack of information or suboptimal incentives. Either way, one of the goals of financial regulators is to reduce unwanted herding to a minimum and to deviate the power of herding toward wealth maximizing directions by providing reliable information to the market, monitoring in order to try and prevent the unwanted effects of bubbles which are created due to herding, and solving credit crunches once they have already been formed.

Efficient Allocation of Financial Resources and Strengthening Investors’ Confidence

Prudential regulation is also necessary in order to allocate financial resources efficiently. The financial market and the institutions operating in this market are essential for economic growth. Banks, insurance companies, the stock exchange, and the likes allow for the concentration of savings and for the efficient allocation of these resources to investment projects that generate economic growth. Financial regulators play a crucial role in reducing information asymmetries with regard to products and providing for a quality label for the financial institutions and for the financial stability of the country in which these institutions

operate. This in turn strengthens investors' confidence and allows them to invest not only in the financial institutions but also in the country itself, knowing that, in high probability, their investment will be returned, sometimes with a profit.

Providing Information to the Market

A financial regulator plays an important role in providing information to the market, mainly through disclosure requirements, which in turn helps the market assign the right price tag to the products (Hayek 1945) and prevents the problem of a market for lemons (Akerlof 1970). In some cases, regulation sets minimum standards for products, and by doing so, it helps clean the market from lemons. Minimum standards are also needed in order to prevent adverse selection, i.e., to prevent "good" or "careful" firms from being driven out of the market.

As banks race for higher profits, they drive risk management criteria down, a situation which may lead to the collapsing of the system. Without regulation, the dominant strategy of each bank is not to invest in appropriate risk management due to the fact that risk management is costly as it restrains the business from acting more aggressively and therefore cuts down on short-term profits. The Nash equilibrium is then set on all banks not investing in appropriate risk management and eventually collapsing. Moreover, due to the systemic connections between banks, if one bank behaves irresponsibly and collapses it might bring down other banks, including those banks that have behaved responsibly in managing their risks while giving up on the extra profits attainable from high-risk, high-reward bets. Financial regulation is needed in order to solve this race to the bottom by setting common minimum standards and insuring compliance with the standards. Such standards will not always differ from the standards that would have been set by the industry if each financial institution could insure that its competitors will also follow these standards. In other words, financial regulation is sometimes useful in order to coordinate competitors in situations in which the Nash equilibrium dictates that each firm defects, even though it is in their interest to cooperate.

The Rationales for Conduct of Business Regulation

Over the years, scholars have played with the idea of an "efficient" financial market, i.e., a market in which there are no information gaps or asymmetries, in which the price of securities accurately reflects the value of the firm and in which investors have access to all the relevant and needed information and are able to analyze it properly (Sharpe 1970). In such a market, agency problems, externalities, and moral hazard would not exist. Therefore, in such a market, there would be no need for regulation as financial regulation is costly and therefore should be avoided whenever possible. The rationale for financial regulation, as for all regulation, is to correct such market failures and imperfections.

Asymmetric Information

The problem of asymmetric information and lack of ability to assess the financial product are enhanced by the existence of products which mature over a large number of years. Such products include pension funds, insurance policies, options with a long duration date, saving accounts which are closed for a long period of time, funds, current accounts, etc. Moral hazard issues may come into play causing the firm to behave differently prior to the purchase of the product then post the purchase. There is no way, other than regulation, to prevent this from occurring. For this reason, regulation enforcing disclosure is essential (Kurlat and Veldkamp 2015). But simply providing the consumers with information is not always enough. The existence of complex financial products makes it difficult for unprofessional customers to monitor the financial institution.

Monitoring

One of the goals of financial regulators is to monitor financial enterprises and assist in monitoring investments and management performance in these firms. Financial regulators are better equipped to monitor financial products, also due to the fact that they develop the relevant expertise in monitoring over time. Monitoring is important

in this market as one of the attributes of financial products is the fact that the contracts attached to the products are usually long-term contracts. This in turn creates several problems among which are principle-agent and monitoring problems. Another monitoring role of financial regulators comes into play with reducing information asymmetries with regard to risk. Due to the benefits of economies of scale, expertise, and the high cost of monitoring for private consumers, it is economically rational to leave the responsibility to monitor financial products partially in the hands of the financial regulators (Baldwin et al. 2012).

Consumers' Behavioral Biases

In consumer contracts, sophisticated firms will try and make use of consumers' behavioral biases in order to expropriate more profit. Competitive forces push sellers to take advantage of their consumers. Financial regulation is needed also in order to correct for such bias. The first thing that should be considered when we talk about consumer contracts is the existence of huge asymmetries between the sides of the contract. One such asymmetry is characterized by the existence of behavioral biases on the side of the consumer, while the other side is a sophisticated firm taking advantage of these behavioral human flaws (Bar-Gill 2004; Campbell 2016).

Consumers Demand for Regulation and Low-Cost Dispute Settlement Mechanism

Consumers themselves demand regulation in order to satisfy their need for quality reassurance. Consumers are aware of the fact that financial markets are highly complicated and require a degree of expertise; most consumers are aware of the fact that they themselves do not possess such expertise, and so most consumers would like an external regulator to monitor and set a certain level of standard to the financial industry.

Furthermore, in lack of a financial supervisor, each consumer/investor is left on his or her own to deal with injustices caused to him or her by the financial institution. The existence of a financial regulator provides the consumer/investor with an address to which he or she can turn to in order to

complain about unjust behavior on behalf of the financial institution. This in turn reduces the need to turn to courts in order to solve petty disputes. Moreover, the existence of a financial regulator enables all consumers to complain without distinguishing between them on the base of their wealth, providing them with low-cost dispute settlement mechanism. This in turn induces the financial institutions to treat their consumers fairly.

Interim Summary

Over the years, a number of positive theories have been developed in order to explain how and when does government intervention in markets occur and what drives changes in regulation. A few different approaches have been used to study this issue, one of which relates to "public interest": regulation is essential in order to correct market failures resulting from externalities and to fix the information gaps between the industry and the consumers. From this perspective, regulation is needed in order to enhance social welfare.

A key challenge to this approach lies in the fact that regulation is not always optimally designed to enhance social welfare – there are many cases in which designing the regulation differently would be more beneficial from a social welfare point of view, yet it is not done. Why? The simple answer would be due to costs.

What Are the Costs Associated with Financial Regulation?

There are many different types of costs which prevent the regulator from reaching an optimal solution. When we talk about the optimal design of the financial regulators, it is important that we take these costs into account (Enriques 2014). Costs are also related to the test of proportionality. In order to enact new regulation under any OECD country regime, there should be (i) a public interest which the regulation comes to

advance, (ii) a rule of law enabling the regulator to regulate, and (iii) the regulation should be proportionate to the goal it is trying to achieve. Among the costs of financial regulation, we can list the following:

Capture of the Financial Regulator

Regulation has major distributional effects and is costly to the regulated firms, because it restricts them from operating in a way which maximizes their profits and, if effective, makes them internalize their costs. Therefore, it is in the interest of the financial firms to effect the regulation they will have to comply with and limit what they perceive to be its “damages” to them. This is also known as the “private interest” theory of regulation or the economic theory of regulation (Bernstein 1955; Stigler 1971; Peltzman 1976; Enriques and Hertig 2011). This theory describes the regulatory process as a competition between two interest groups, in which the well-organized, well-coordinated group is able to extract rents at the expense of the more dispersed, less informed groups (Becker 1983). Under this theory, the strong organized interest group is able to capture the regulator and influence its regulation to promote the benefits of the regulated firms. A captured regulator will act according to the interests of the regulated firms rather than in accordance with its mandate which is to promote the common good. From a welfare perspective, a captured regulator might yield one of the most serious costs associated with financial regulation as a captured regulator has the capability to heavily damage the general welfare in order to promote other, sometimes personal, goals.

Cost of Mistakes

Another cost that is related to financial regulation is the cost of a mistake being made by the regulator. If the regulator issues regulation based on wrong perceptions of either a market failure or the approach which is needed to be taken in order to correct it, then such mistake will spread out to the entire regulated market (Romano 2014). This is sometimes referred to by the literature as “macroeconomics distortions.” Such distortions could increase existing market deficiencies and

undermine the objectives intended for the regulation in the first place. In some cases, mistakes in financial regulation may increase the magnitude of a financial crisis or even cause it.

Systemic Risk Arising from Financial Regulation

As discussed earlier, one of the major goals of financial regulation is to prevent systemic risk. However, financial regulation may by itself cause systemic risk if it is deficient and especially if it spreads to a global level. Treaties or global regulations are often a political compromise between the countries involved and thus are not easily adjustable for the needs of a specific market (Romano 2014).

Another source of systemic risk resulting from regulation might stem from a regulatory attitude promoting complex and detailed regulation. This attitude might cause financial institutions to rely solely on the regulation without using common sense to protect against dangers which were neglected by the regulation or unexpected changes in risks on the one hand, and cause consumers, investors, internal auditors, and financial regulators to feel overly confident with regard to the stability of the financial system on the other hand.

Distortion of Competition

Financial regulation often creates barriers to entry. The need for a bank license and collateral requirements are two prominent examples. As regulators are concerned with stability and preventing systemic risks, they might tend to be “overprotective” and put up demands which leave “large margins.” Such an attitude may prevent or discourage new firms from entering the market (Hendrickson 2011). Concerns of systemic risks may lead the financial regulator to keep financial institutions “alive” even in situations where otherwise, given a fully competitive market, would have led to the restructuring or removal of the financial institution from the market. Financial regulation may also interfere with competition within the market itself by demanding exorbitant disclosure – if all information is disclosed there is less room left for competition.

Costs of Fragmentation of the Regulatory Regime

Fragmentation in the context of regulation is a term used in order to describe a situation in which there is more than one supervisory authority active in the market. In such a case, we would consider the market to be “fragmented” from a regulatory point of view as there is more than one regulator imposing regulatory policies and demands on the regulated firms in the market. This situation may lead to severe cooperation issues between the regulators and cause problems with the flow of information between the different financial regulatory bodies (Jabotinsky 2017). Fragmentation incurs costs; the existence of several regulators acting without coordination in the market may lead to inefficiencies and cause regulatory arbitrage on the part of the regulated institutions. This in turn implies the formation of conflict or jurisdiction and lack of regulation or overlapping regulation. Moreover, the existence of several regulators increases the risk of incoherent regulation resulting in uncertainty on the part of market participants.

Others

Administrative costs – Regulatory agencies, like any agency, cost money. As financial regulation is a public good, the financial regulator is financed by the government using public money.

Cost of compliance on behalf of the financial institutions – Regulatory compliance demands place a heavy financial burden on financial institutions, especially on smaller market participants. The cost of regulation exhibits strong economies of scale, sometimes resulting in smaller banks being “penalized” twice as much as larger institutions.

Innovating around the regulator – A profit-seeking firm will go the length to extract more profit from the market; thus, it will go to great efforts to find a way to innovate around the regulation. In some cases, cases which do not provide the market with a new product or service that is materially different from the existing products on the market, innovating around the regulation is costly and does not generate greater social welfare.

Moral hazard resulting from a rigid regulatory regime – A rigid, detailed, and protective regulatory regime might remove the responsibility from the financial institution’s employees and transfer it to the employees of the financial regulator, thus causing the employees of the financial institution to behave recklessly.

Summary

As has been discussed above, financial markets do have special attributes which require regulatory intervention. They are complex markets which are abundant with asymmetric information, moral hazard, externalities, and agency problems. They are markets in which products mature over a long period of time causing a need for regulatory monitoring which is exacerbated by consumer demand for regulation and economies of scale in monitoring. Moreover, the financial firms in these markets are crucially important from a systemic point of view to the health of the economy in general.

Having said all that, financial regulation is costly. Regulation in general should only be enacted if the costs of implementing it are lower than the benefits derived from what it seeks to achieve. That is especially true for the financial markets, as the health of these markets affects the social welfare of society as a whole.

Moreover, with regard to financial supervision, it is crucial that the responsibility for the actions of the financial institutions and for compliance with the laws and regulations remains in the hands of the financial institutions’ employees and management. Leaving the responsibility in the hands of the financial institutions themselves is important also from the aspect of minimizing regulatory mistakes and systemic risk caused by regulation. If financial firms are provided with regulatory guidelines instead of strict rules, this helps in diversifying the market. In the era of global systemic risk, this is crucially important.

Consumers themselves should be entrusted with the responsibility to monitor what their financial institution is doing with their assets. In order to do so, financial regulation should force

financial institutions to provide consumers with easy to understand data.

Regulation is not about quantity but about quality. The “right” kind of regulation gives the financial institutions the incentives to act in a way which enhances social welfare and reduces market failures.

Fiscal Federalism

Philip C. Hanke¹ and Klaus Heine²

¹Department of Public Law, University of Bern, Bern, Switzerland

²Rotterdam Institute of Law and Economics, Erasmus School of Law, Erasmus University Rotterdam, Rotterdam, The Netherlands

Abstract

Fiscal federalism is concerned with the optimal level of centralization or decentralization of state activity. The early literature attributed the central government two functions: ensuring allocative and macroeconomic stability on the one hand and assistance of the poor (redistribution) on the other hand. A second generation of fiscal federalism went beyond the realm of public economics and added aspects of political economy and to the debate. In the context of European integration, these questions are of particular relevance, with migration and the sovereign debt crisis being two examples addressed in this entry.

Definition

Fiscal federalism is a subfield of public economics discussing which functions of the public sector and appropriate instruments to carry out these functions are best centralized and which should be allocated to decentralized levels of government (see, e.g., Kenyon and Kincaid 1991; Oates 1999).

Introduction

Roughly one half of the world's population lives in systems of government where sovereignty is constitutionally divided between a central government and constituent political entities such as states or provinces, which in turn can also share their competences with local units such as cities or counties. Some countries, although not

federations de jure, have devolved significant policy-making powers to local or regional levels of government (e.g., France or the United Kingdom). At the same time, the process of European integration is creating a federation sui generis. It can thus be studied how to best allocate functions of the public sector and policy instruments vertically to carry out these functions among the different levels of government.

Broadly speaking, the scholarship on fiscal federalism can be divided into a first and a second generation (Qian and Weingast 1997; Oates 2005). The earliest formulations of the first-generation theory of fiscal federalism (as in Musgrave 1959; Oates 1972) attributed to the central government two functions. One was the basic responsibility for macroeconomic stability. With highly open local economies, decentralized governments cannot affect local levels of employment and prices using the means of monetary policy. The other one was the assistance of the poor. Since individuals and businesses are mobile, redistribution should be done at higher levels of government to prevent net contributors from relocating to a jurisdiction with a lower tax burden. Second-generation economic theories of fiscal federalism expand earlier theories by adding components of political economy (public choice) and political science.

Consequently, this entry follows the historical development from first- (section "[First-Generation Fiscal Federalism](#)") to second-generation federalism (section "[Second-Generation Fiscal Federalism](#)"). Section "[Fiscal Federalism in the EU](#)" specifically discusses federalism within the context of the European Union and gives two concrete examples: the case of migration and the European sovereign debt crisis. Finally, section "[Conclusion](#)" concludes.

First-Generation Fiscal Federalism

The public finance literature in the 1950s and 1960s came to an important finding, namely, that there should be a "separate governmental institution for every collective good with a unique boundary, so that there can be a match between

those who receive the benefits of a collective good and those who pay for it" (Olson 1969, 483). First-generation fiscal federalism is thus primarily concerned with a fundamental trade-off: providing public goods and services through centralized policy-making is suboptimal because of the divergences in local tastes and conditions, while decentralization can lead to inefficiencies because local governments do not fully internalize interjurisdictional externalities.

The Tax Assignment Problem

The tax assignment problem, coined by McLure (1983), addresses the fundamental normative question which taxes are best suited at which level of government. It is assumed that people, goods, and resources can easily move between lower-level jurisdictions, while there is little or no mobility at the higher (e.g., national) level. At the starting point is the Tiebout (1956) model, in which mobile individuals can choose between bundles of taxes and public goods provided by a large number of local communities. Since people have different preferences regarding those bundles, they will move to the community that maximizes their personal utility. Through this mechanism, it is possible to provide public services at a decentralized level. Since the individual preferences are then matched with the local governments supplying exactly the public goods demanded, total welfare is increased. This proposition was formalized as the so-called decentralization theorem in Oates (1972). It follows that taxing mobile individuals through a decentralized system of government is impossible or causes distortions in resource allocation as individuals bear costs to avoid taxation. As the subsequent work of Oates and Schwab (1991) and Oates (1996) shows, thus mobile factors should be taxed with benefit levies. Non-benefit taxes, that is, those that usually have some redistributive effect, should be allocated to the central government. Nevertheless, many local jurisdictions still maintain local redistributive schemes.

The decentralization theorem also faced the question why a central government is inherently unable to produce the optimal outcome. The answer is twofold. First, there is an information

problem: local governments are closer to their constituencies and thus have a better knowledge of their residents' wishes and requirements, as well as of the costs involved in fulfilling them. Secondly, the idea that a central government fine-tunes its policies to the needs of local jurisdictions collides with the general principle of equal treatment at the national level, where a certain character of uniformity is expected from the central government.

Olson's (1969) concept of fiscal equivalence, where local public goods were provided in such a way that the geographical scope of benefits coincided with the boundaries of the jurisdiction financing them, led to a practical problem: designing a federal system without any spillovers between jurisdictions could hardly exist (Oates 2005). Thus, with decentralized provision of local public goods, it is necessary that the central government provides subsidies to the local jurisdictions in order to internalize the benefits of positive externalities between the local governments. Another role for the central level government is less guided by efficiency concerns than it is by equity considerations: by redistribution from rich to poor jurisdictions, it can contribute to the cohesion of economically differently developed regions.

The early literature on the tax assignment problem already recognized the importance of hard budget constraints, that is, that jurisdictions cannot export parts of their tax burden onto other jurisdictions. Otherwise, local budgets would be inflated beyond efficient levels. Nevertheless, vertical transfers among entities in a federal state are common. While some countries have equalizing transfers from richer states or provinces to poorer ones (through the federal level), some other countries such as the United States know them primarily at the level of the states, that is, there are equalizing grants among local jurisdictions. Through such equalizing grants, spillover benefits can be internalized. There are also equity considerations for equalizing transfers, while the verdict is still out on their efficiency effects. It is not clear whether they promote economic growth in poorer regions or whether they inhibit the adjustments necessary for economic development.

Furthermore, they play a role in ensuring a progressive tax system and correct the regressive effects of decentralized taxation.

The more recent literature on fiscal federalism has in further detail emphasized the importance of hard budget constraints (see below).

Economies of Scale

Providing public goods and services comes at a cost. If these costs have a fixed component (or more general have the feature of subadditivity), then decentralized provision means that these fixed costs have to be borne by each jurisdiction providing it and the total costs will be larger than if the central government incurred them. Thus, public goods and services with high fixed costs should rather be centralized, whereas goods and services with low fixed costs can be decentralized. This point can be applied not only to traditional public goods and services but also to law as a public good, which implies strong network externalities and may lead to path dependencies in the law provision (Heine and Kerber 2002).

Laboratory Federalism

Decentralized government can facilitate experimenting with new laws and regulations in order to assess their suitability. In a dissenting opinion to the US Supreme Court's 1932 *New State Ice Co. v. Liebmann* ruling, Justice Louis Brandeis argued in favor of legal experimentation: "It is one of the happy incidents of the federal system that a single courageous State may, if its citizens choose, serve as a laboratory; and try novel social and economic experiments without risk to the rest of the country" (*New State Ice Co. v. Liebmann*, 285 U.S. 262 at 285). This idea has been taken up by theories of federalism. In this view, lower-level governments can experiment with new policies, which, if deemed successful, can later be implemented at the national level. Oates (1999) gives the examples of unemployment insurance and emissions trading. The recent decision of the Supreme Court on the unconstitutionality of any prohibition of same-sex marriages comes to mind as a more recent example of a case where experimentation at the state level led to subsequent complete adoption at the national level.

The diffusion of new policies does not necessarily have to be vertical, but can also be horizontal. A basic problem with such experimentation is that it is better not to be the first to implement a new policy, but to rather observe other jurisdictions innovate and then free ride on their learning experience. In other words, there is a positive information externality which potentially leads to too little experimentation (see, e.g., Rose-Ackerman 1980; Strumpf 2002). However, there are examples in which jurisdictions are very engaged in horizontal interjurisdictional competition, as the example of the US State Delaware showcases with regard to corporate law (Romano 1993).

Interjurisdictional Competition

With decentralization comes competition among lower-level governments. Through various policy instruments, such as tax rates but also, e.g., environmental regulation, they seek to attract capital investments.

It is still an open question under which conditions horizontal competition among governments is efficiency enhancing and when it is destructive. The models of Oates and Schwab (1988, 1991, 1996) liken interjurisdictional competition to perfect competition in the private sector. Local governments set efficient bundles of public goods and taxes in order to compete among each other for mobile capital. The result is a "race to the top." For these results to hold, a series of assumptions has to hold, namely, that jurisdictions behave as price takers in capital markets, that public officials act in the interest of the common good and are not self-interested, and that all necessary regulatory instruments are available to them in order to carry out the desired policy.

Other models, but also the Oates and Schwab models if the abovementioned assumptions are not met, emphasize the possible outcome of a "race to the bottom," in which competition is detrimental to total welfare. A typical example is the setting of environmental standards. If politicians are primarily concerned with attracting businesses and enlarging the local tax base, then they might set excessively lax environmental standards (Oates and Schwab 1988).

While mobility is an important factor in interjurisdictional competition, it has also been argued that the simple fact of observing policies in other jurisdictions – what has been called “yardstick competition” (Salmon 1987) – can be enough to exert pressure on politicians to implement similar ones. The presence of decentralized government influences decision-making and constrains the set of actions (e.g., the possible tax rates) even if local governments are not in a position strong enough to actively participate in the competition (Kenyon 1997).

Second-Generation Fiscal Federalism

While fiscal federalism is concerned with the optimal level of centralization or decentralization of state activity, it also provides a framework to explain and predict the constitutional arrangements found in practice. Second-generation fiscal federalism thus goes beyond the realm of public economics and draws its inspiration from public choice, information economics, the theory of the firm, organization theory, and contract theory (Oates 2005). It also profits from input from adjacent disciplines such as political science.

Market-Preserving Federalism

On a different level of analysis than the public economics approaches mentioned above, federalism can also be seen as an institution to preserve a market economy with well-defined property rights. In a strain of literature in the tradition of new institutional economics, federalism as a system can be designed as a mechanism limiting how far a country’s political class can encroach on its markets. In a seminal article, Weingast notes a “fundamental political dilemma of an economic system,” namely: “A government strong enough to protect property rights and enforce contracts is also strong enough to confiscate the wealth of its citizens” (Weingast 1995, 1). Property rights and the enforcement of contracts are thus only secure if the state is limited in its ability to confiscate wealth.

In subsequent articles, five conditions are established in order to create and to preserve market-preserving federalism. First, there “exists

a hierarchy of governments with a delineated scope of authority (e.g., between the national and subnational governments) so that each government is autonomous in its own sphere of authority.” Secondly, “the subnational governments have primary authority over the economy within their jurisdictions.” Thirdly, “the national government has the authority to police the common market and to ensure the mobility of goods and factors across subgovernment jurisdictions.” Fourthly, “revenue sharing among governments is limited and borrowing by governments is constrained so that all governments face hard budget constraints.” Finally, “the allocation of authority and responsibility has an institutionalized degree of durability so that it cannot be altered by the national government either unilaterally or under the pressures from subnational governments.” While the first condition is inherent to federalism, the other four ensure its market-preserving character.

In a somewhat similar vein, Inman and Rubinfeld (1998) argue that federalism is next to rights enumerated in the constitution, and the separation of powers between branches of the central government is the third possible line of defense in protecting rights of citizens. The federal form, they argue, can also encourage participation, as individual votes are more likely to be pivotal in small jurisdictions and accessing as well as monitoring politicians is easier.

Self-Interested Agents in Political Processes

An important expansion on the initial literature on the economics of federalism is the insight that the public officials do not necessarily act in the interest of an elusive general interest, but can also act as self-interested actors. The same also applies to voters who also maximize objective functions in the context of political processes. With these assumptions, the principal-agent model becomes the main approach. The relationship between the principal and the agent is characterized by asymmetric information and imperfect monitoring, while the outcome has a stochastic component. The contract between the two thus has to be based on the observed outcome. With multiple levels of government and different societal actors, there are

many possible interpretations of who the principal is and who the agent is. For instance, in what is referred to as “administrative federalism” (Inman 2003), the public officials of the local governments can be considered the agents of a central government, which has certain objectives. In other models of fiscal autonomy, the principal-agent conflict of interest is between the electorate and elected officials, and elections constitute incomplete contracts with unverifiable information. The conclusion from these models is usually that decentralization improves accountability and control (see, e.g., Seabright 1996; Tommasi and Weinschelbaum 2007).

Information Problems

The early literature on fiscal federalism already highlighted the information problem present in policy-making and understood it as an argument in favor of decentralization. Second-generation fiscal federalism elaborates a bit further on where this information comes from. At first, there is the question why the central government cannot, through various means, acquire detailed information on local needs. As Cremer et al. (1996) point out, such activities are costly, and obtaining such information is more important and valuable to local public officials than it is to those of the central government. This creates the fundamental problem that it is generally assumed that the central government has no significant issues collecting information on the needs regarding public goods and services provided at the national level. Additionally, the information problem creates the question how the central government is then able to set the Pigouvian subsidies to compensate local governments for positive interjurisdictional spillover effects. It can only do so if it has accurate information on the valuation of the spillovers at the local level. Nevertheless, it is argued (e.g., in Oates 2005) that an outcome with imperfect subsidies is still better than one where externalities are ignored altogether.

Functional, Overlapping, Competing Jurisdictions (FOCJ)

A proposal for a new kind of federalism lies in the concept of functional, overlapping, competing

jurisdictions. Advocated in the late 1990s by Bruno Frey and Reiner Eichenberger (1999), the government is divided into organizations called FOCUS. The idea is that every such entity is functional, that is, it deals with a specific, delimited matter, such as education, public safety, or infrastructure. As a result, there are several, overlapping FOCJ covering certain individuals or regions. Individuals can then choose which FOCUS applies to them for which policy field. If the function is territorially bound, then a local entity (“commune”), such as a town, determines democratically which FOCUS it belongs to. There is thus competition between FOCJ. A FOCUS, once chosen, has the power to levy taxes. It is thus a jurisdiction.

The advantage of these FOCJ, so the argument, is that the concept combines four important aspects of the economic theory of federalism. First, fiscal equivalence can be achieved. Secondly, the boundaries are well defined so that new members of these clubs can be charged optimally, namely, at the marginal costs. Thirdly, the voting by foot mechanism is enabled through exit and entry. Finally, there is political competition through democratic processes and thus a “voice” mechanism.

Such a system that relies less on geographical units can be found in several federal settings around the world and in history. The United States knows the concept of “special districts,” Swiss local units can and do build functional and overlapping special communes, Germany knows “special purpose associations” (*Zweckverbände*), and the European Union carries strong traits of FOCJ as well (e.g., the monetary union, the Schengen Area, and others).

Fiscal Federalism in the EU

There are two phenomena taking place at the same time in Europe. First, countries have devolved some competences from the central government to local or regional levels (e.g., the creation of *régions* in France and devolved governments in the United Kingdom), thus creating more decentralized policy-making. Secondly, there is,

at the same time, the process of European integration, which gradually allocates competences to the European institutions. What might appear as contradictory at the first glance can very well be interpreted as a more nuanced approach to fiscal federalism.

The Principles of Conferral, Subsidiarity, and Proportionality

The structure of European federalism is laid out in the Treaty on European Union (TEU): “The limits of Union competences are governed by the principle of conferral. The use of Union competences is governed by the principles of subsidiarity and proportionality” (Art. 5(1) TEU). Under this principle, “the Union shall act only within the limits of the competences conferred upon it by the Member States in the Treaties to attain the objectives set out therein. Competences not conferred upon the Union in the Treaties remain with the Member States” (Art. 5(2) TEU).

In other words, the EU does not have the authority to appropriate competences to itself. This distinguishes it from other federations, where in some fields the national legislature has the so-called competence-competence (the power to assign competences) and can reassign competence between the federal and the sub-federal level through a regular law and not necessarily through a constitutional amendment. The EU’s competences are conferred through the TEU; thus, any change would require a treaty change, which is an intergovernmental procedure involving all 28 Member States and therefore lengthy and inert. This inertia also leads to a problem in the other direction: once the EU has a certain competence, it is very difficult to devolve policy responsibilities from the supranational back to the national level (Kirchner 1998).

Article 5(3) states: “under the principle of subsidiarity, in areas which do not fall within its exclusive competence, the Union shall act only if and in so far as the objectives of the proposed action cannot be sufficiently achieved by the Member States, either at central level or at regional and local level, but can rather, by reason of the scale or effects of the proposed action, be better achieved at Union level...”

Finally, the principle of proportionality requires that “[...] the content and form of Union action shall not exceed what is necessary to achieve the objectives of the Treaties [...]”

Current Challenges

Migration

In the European Union, migration is regulated at several levels of government. While the freedom of movement of EU citizens is a fundamental freedom well entrenched in EU law, admission of third-country nations (TCNs) is primarily left to the member states. The *Schengen Area* has a joint visa policy, and the *Dublin system* constitutes a joint framework for a decentralized system of examining applications for asylum.

The decentralized treatment of TCNs entails significant restrictions on their mobility within the EU. For instance, a recognized refugee is not allowed to relocate to a different EU Member State within the first 5 years of residence in the country that granted the refugee status. In this sense, the current migration regime challenges the common assumption in economic theories of federalism of complete mobility within a federation. Asylum seekers, who according to the *Dublin system* are required to request asylum in the EU member state that they first set foot in, might thus be stuck in a place that is not optimal from an allocative perspective (e.g., if their skills are more sought after in a different Member State).

The European Sovereign Debt Crisis

During the debt crisis that started in 2009, several Eurozone member states (Cyprus, Greece, Ireland, Spain, and Portugal) were unable to fulfill their obligations toward their creditors. They thus required assistance of the European Central Bank (ECB), the International Monetary Fund (IMF), and the European Financial Stability Facility (EFSF), a special purpose vehicle established by the EU member states in 2010, which was replaced by the European Stability Mechanism (ESM) in 2013.

In terms of fiscal federalism, the debt crisis showed that the hard budget constraint in the relationship between member states and the EU as a federal system of open economies could not

be upheld. This does not necessarily mean that large-scale transfers among member states through the EU institutions are not economically justified. Furthermore, fiscal federalism theories in some instances do recognize the presence and necessity of interjurisdictional transfers.

Tax Harmonization

The European Union is currently discussing harmonizing taxes and tax bases within the Union. VAT harmonization has already taken place with the intention of creating a level playing field for firm operation across the EU. The currently principal legal source is Council Directive 2006/112/EC of 28 November 2006 on the common system of value-added tax. The EU harmonized not only VAT law but also limited the number of different VAT rates the Member States can set for various types of goods: there is a minimum 15 % “standard rate,” and countries can apply two reduced rates of at least 5 % on certain goods. The list of goods eligible for the reduced rates is set at the EU level. From a fiscal federalism point of view, it is debatable why the EU should regulate the VAT rates set by the Member States as it is not clear what the externalities in a nonregulated setting would be.

Another ongoing project is the establishment of a so-called Common Consolidated Corporate Tax Base (CCCTB). This proposal, which was developed by the European Commission, aims at formulating mandatory common rules on how to calculate the tax base and at allowing companies to report their tax results consolidated at the European level. The individual Member States would then still set the actual tax rate. From a federalism theory point of view, this measure seems to reduce the information problems present in intra-European trade while not limiting the ability of jurisdictions to set their own tax rates. However, one may conceive the CCCTB also as a first step toward the “cartelization” of tax policies of the Member States to the detriment of tax payers.

Conclusion

Taking the insights from economic theories of federalism seriously means to recognize that

both centralizing and decentralizing ideologies are wrong. As Olsen pointed out, “there is a case for every type of institution from the international organization to the smallest local government” (Olson 1969, 483). Theories of fiscal federalism can contribute to assign specific competences to the appropriate level of government. Second-generation federalism added to this insight that the separation of powers across different vertical levels of government is per se a precondition to sustain a functioning market economy that honors property rights.

Definition

Fiscal systems gather all the taxes and contributions levied to fund the State. These taxes and contributions share the characteristics of being compulsory and unrequited payments to the government, in the OECD sense. Historically, fiscal systems have shown their scalable nature as they are embedded in larger economic, social, political, and cultural systems. It is possible to distinguish the positive analysis and the normative analysis of fiscal systems. The positive analysis enlightens fiscal systems characteristics in terms of tax structure, while the normative analysis questions the qualities of a *good* tax system.

Positive Analysis of Fiscal Systems

Fiscal systems are large collection processes aiming to fulfil the imperatives of financial returns, efficiency, and fairness associated with State intervention, as summarized by Musgrave in 1959, with the three-function framework. The first function, of resource allocation, is to see that resources, generated through taxes, are levied and used efficiently. The second function, of revenue redistribution, deals with the fair distribution of income. The third function of stabilization is to ensure the achievement of high employment, price stability, and growth. Positive analysis of fiscal systems describes their tax structures. From the nineteenth century, the observed growth of the State, as a result of the economic development and greater public intervention, give tracks to explain the extension and diversification of tax structures. Comparison of taxation patterns among countries enlightens the high degree of diversity existing in fiscal systems. Still, groups of fiscal systems with common characteristics can be distinguished. An immediate split would be between developed countries’ fiscal systems and those of developing countries. Developing countries’ systems differ due to limited economic activity and weak accountability standards that result in a restricted set of usable tax bases and low administrative power.

From the beginning of the twentieth century, a similar diversity in the types of taxes levied is to be

found in developed countries. This implies diversity both in terms of the tax base (commodity tax or excise, land taxes, custom duties, and income tax) and tax schedules (lump sum tax, proportional or progressive rates, brackets, exemptions). Still, both the world wars and the development of the welfare State by the middle of the twentieth century have changed the dimension of fiscal systems, with a large and permanent increase in taxes, especially income taxes. This growth of State activities is described by the Wagner law (Bird 1971), as well as the displacement and ratchet effect (Peacock and Wiseman 1961). Over the 1950s and the 1960s, in turn appeared the VAT tax that was implemented progressively in European countries and most developed countries. In the end, current OECD countries' tax systems show common trends in terms of the greater variety in the types of taxes used to collect a higher percentage of GDP of public funds; however, there also exists some degree of country-specific heterogeneity, notably in the total tax pressure and the share of tax revenue derived from each type of tax. Effectively, OECD countries can be separated into a low-tax group and a high-tax group, (Fig. 1, OECD 2017). All rely on the same set of taxes: income taxes, property tax,

consumption taxes, social contributions but with different weights. Another common feature is the fact that they take into account the specificities of family structures, while the way to deal with this issue varies widely across countries. Below table gives an overview of the different weights OECD countries attach to each type of tax. It shows that major differences are to be found in the weight given to social security contributions, overall weight and types of consumption taxes used, importance of capital taxation (corporate and property taxes).

Normative Analysis of Fiscal Systems

The normative analysis of fiscal systems details the imperatives for a *good* fiscal system and as a consequence throws another light on the trend towards diversification of tax structure. A *good* tax system should be able to collect private money in the most efficient but also fair manner, without weakening the legitimacy of the tax, so that there is no rise in noncompliance. If these conditions are met, optimality is reached if not, tax reforms become necessary to avoid resistances, and, at worse tax revolts.

Fiscal System, Fig. 1 OCDE tax system structures

Nevertheless, one difficulty is that efficiency and equity principles may oppose one to the other.

A good tax system is an efficient one. The efficiency principle states that the levy should provide the required level of resources to the State, under the constraint of the neutrality principle, that is, it should avoid distorting the initial economic decisions (Salanié 2011). Yet, as a matter of fact, taxes always impact economic decisions and resource allocation if they alter work incentives and generate a substitution of work with leisure. The same will hold for saving, investment, or innovation decisions. By doing so, taxes generate an excess burden measured through the deadweight loss, which is a loss of well-being due to these substitution effects. As a consequence, it is important to be careful about any effect that taxes have on economic efficiency. This is needed to decrease the deadweight loss associated with tax implementation but also because of its potential impact on growth and the macroeconomic equilibrium. Each type of tax instrument results in a specific excess burden, as detailed in the optimal taxation literature. Under the constraint of feasibility and enforcement, this may guide tax structure evolution. For instance, the lump-sum taxation, which is entirely disconnected from the economic decisions of an agent, benefits from a major advantage in terms of efficiency, but is rarely implemented because of equity concerns.

A good tax system is a fair one. The fiscal equity principle implies a fair distribution of the tax burden among the taxpaying population. It questions the initial distribution of the tax burden but also the final one resulting from taxpayers' *tax shifting* strategies (Prest 1955). *Tax shifting* corresponds to the shift of the tax burden from the legal taxpayer, as pointed out in the tax law, to a final and effective tax bearer. This analysis is the core of the incidence theory (Fullerton and Metcalf 2002). Thus, to go deeper into the analysis of fiscal system fairness, it is necessary, on the one hand, to estimate the tax burden any taxpayer should face and, on the other hand, to define principles of a fair distribution of the burden among a large set of heterogeneous taxpayers. Fiscal theory states that there are two ways to estimate the tax burden. The first one is to charge

each taxpayer with taxes equivalent to the benefits he derived from public services and public goods. This refers to the *benefit approach* that goes back to Smith (1776/1976) and that was refined in the twentieth century by economists like, among others, Wicksell (1896/1958), and according to which a social contract links citizens and the State. Nevertheless, implementation of such a criterion is complex due to the very nature of public goods, which are characterized by non-excludability, nonrivalry, and indivisibility. A second option is to distribute the tax burden according to taxpayers' tax capacity, that is, their ability to pay for public expenses.

The implementation of this second principle raises, in turn, several difficulties and questions about tax capacity estimates and the criteria for the fair repartition of the tax burden based on them. Ability to pay tax depends on the economic power of taxpayers and there are at least three relevant indicators to measure it: income, wealth, and consumption. In the heterogeneous population of taxpayers, one may well encounter, side by side, an employee and an annuitant, whose tax capacities may be estimated on the basis of income and wealth, respectively. For such reasons, and as each indicator would lead to a different distribution of the tax burden among the population, all fiscal systems combine several fiscal bases. This constitutes another factor justifying the evolution of fiscal systems' structure toward increasing – and to some degree, natural – complexity. At this stage, the question of the fair distribution of the burden among taxpayers still remains. Two rules deal with the thorny question of taxpayers' relative situations. The first one is known as the horizontal fairness principle and states that those taxpayers that are characterized by the same tax capacity should be treated identically. The second one, the vertical fairness principle, is more controversial and states that taxpayers who differ in their tax capacities should be treated differently on the basis of what is considered as the *acceptable level* of unfairness. For such reasons, fiscal systems are tributary of each country's culture and history.

Away from this subjective consideration, the chosen tax structure gives the big picture showing

which taxpayer is supposed to bear the tax burden while incidence theory details and concludes on the effective burden, once *tax shifting* of any kind has displaced it on to the final and effective tax bearer. One direct example of tax shifting could be any increase in selling price justified by an increase in corporate tax. But ways and means to transfer the burden are diverse and marked by a constant innovation, which is the fiscal dimension of the taxpayers' reactions. These tax transfers are nevertheless sensitive not only to economic determinants (labor market structure, demand, and supply elasticity) but also to fiscal technicity, that is, to the type of tax (direct, indirect) and the tax schedule (rates, brackets, exemptions, deductions). Planning, optimizing, avoiding, and evading taxes are also ways to decrease the burden up to, and sometimes beyond, legal boundaries, (Bazart 2002). It undermines efficiency and equity of the system by shifting the burden on somebody else and by constraining collection. In the end, it justifies reforms, such as: increase in some tax rates, increase in collection through specific taxes and tax bases, and introduction of new taxes.

Institutions, Laws and Tax Compliance

The traditional theoretical approach of optimal taxation has offered numerous contributions to the analysis of optimal taxes, relevant tax rates, and in the end desirable structures of tax systems (Mirrlees 1971; Atkinson and Stiglitz 1976; Atkinson 1991). Nevertheless, from the 1970s, the change in economic conditions under the constraint of a bidding budget constraint, and increasing public deficits, has given more importance to preoccupations about tax base erosion, such as tax evasion or avoidance. Reducing the tax gap became a policy option per se.

For such reasons, fiscal systems analysis has developed quickly on new grounds by adding administrative and enforcement dimensions to the debate to handle the diverse aspects of behavioral reactions to taxation. These were initially gathered under the wide definition of tax evasion

and soon under the even wider concept of non-compliance. From the initial work of Allingham and Sandmo (1972) on, decision to evade taxes was modelled as a risky decision. This decision depended on individual characteristics, among which the degree of risk aversion, and on environmental characteristics such as, at first, harshness of deterrent policies and quickly after a large set of factors such as: unfairness of the system, complexity of the system, uncertainty on rules, use of direct democracy. . . . On the one hand, a direct causal link was established between evasion and complexity, uncertainty and unfairness of the system. On the other hand, an immediate set of results supported the deterrent power of audit rates and penalties; but this has, afterward, been mitigated, in time as research provided new insights. Audit rates and penalties have to exist, but increasing deterrence harshness beyond some threshold is not possible and in fact unnecessary. Effectively, there are counter-productive effects to penalization. Observing first that deterrence's effects are nonlinear, decreasing above some threshold values of penalties and/or audit rates and second that procedural unfairness increases evasion (Rato and Gemmel 2012), it became clear that deterrence levels should be kept low. Kirchler (2007) offers a complete and synthetic analysis of the enforcement problem, known as the slippery slope framework. In this theory, enforcement is accepted under a high level of trust in the government, while in the opposite case, it generates resistances. As a consequence, besides deterrence, the concerns about complexity of tax law and fiscal systems as a whole has witnessed an increase in importance in the debates in the Western democracies.

This emphasized the need to focus on the terms of implementation and enforcement of the levy. Besides efficiency and equity considerations, the third pillar of administration is being given greater concern and importance. This refers to a twofold set of costs: administrative costs borne by the tax authorities and linked to its enforcement efforts (Martin (1944) and compliance costs supported by taxpayers while fulfilling their fiscal duties (Slemrod and Sorum 1984). All these costs result, for one part, from the level of transparency,

consistency, ease in understanding of fiscal laws and procedures. In sum, simplicity of the system favors taxpayers' compliance and acceptance of their liability while the reverse holds for complexity of the system, laws, and procedures. Empirical supports to these assertions are numerous, and it is interesting to note that Alm et al. (2010) obtains, experimentally, an increase in tax noncompliance when the tax law is complex; a decrease if in such a context of complexity, the tax administration acts as a facilitator and a provider of services to taxpayer-citizens. Country studies have also shown the importance of simplicity on tax compliance, for instance, Cuccia and Carnes (2001), Marcuss et al. (2013) for the USA, or Blaufus et al. (2017) for Germany. If the evolution of tax systems implies a natural level of complexity, to some point simplification becomes necessary. In western democracies, many reforms are initiated in line with this: for instance, in the UK, where a Simplification Office was experimented in the last decade or in France where withheld income tax is to be introduced. In all cases, reducing compliance and/or administrative costs is at stake.

Tax law thus has to be easily understandable to reinforce legitimacy of the tax, to avoid procedural unfairness, and provide, efficiently, a help by its expressive nature. That is to say that deterrent parameters also stand as a signal of the norm prevailing in the considered society. Their low level does not explain compliance as demonstrated in 1992 by Alm et al. Still they stigmatize that noncompliance is not acceptable and that the rule to follow is to pay due taxes. Norms activation impacts tax decisions (Myles and Naylor 1996; Bazart and Bonein 2014; Lefebvre et al. 2015), and it is crucial to give the good signal about prevailing social norm. Indirectly in sum, simplification decreases the tax enforcement efforts of the tax authority and improves relationships between taxpayers and the collector. As a matter of fact, it seems to be a win-win strategy as in the end fiscal systems are subject to the judgement of those taxpayers who bear the burden and fiscal history provides various testimonies about tax revolts and resistances to the levy when its legitimacy is weakened.

Conclusion

Tax collection is based on the consent of members of a community to fund the public sector. This consent is expressed through the vote of tax law and the act of fulfilling fiscal duties. Still, taxes are also marked from the very beginning by an underlying climate of resistance evident in the use of terms, such as tax liability, duty, and burden. Moreover, as taxpayers can react strategically to taxes on economic, political, and fiscal grounds, they distort efficiency, fairness, and the simple administration of the system. The extent of behavioral economic analysis of the taxation and fiscal system has shown the deep impact that these behavioral responses to taxation (Alm 2012) have on the system's stability and evolution. It underlines the limitations of reasoning only in terms of optimality of tax systems, as the classical optimal tax theory does. On the contrary, it states that there is room for manoeuvre to reconsider, beyond the analysis of the optimal tax system, the gains to be obtained from a correct appraisal of administrative and compliance costs, in line with the most recent tendency to go towards simplification, tighter enforcement efforts against evasion, and more collaboration with the tax authorities (Slemrod and Gillitzer 2013). The tax system in such a case will gain from a balanced consideration of its multidimensional nature.

Fixed Investment

Rafael Llorca-Vivero

University of Valencia, Valencia, Spain

Abstract

In a wide sense, the concept of “fixed investment” refers not only to investment in physical capital but also to expenses directed to other intangible assets such as high qualified labor, R&D, the acquisition of particular knowledge about markets or consumers' behavior, advertising, etc. Fixed investment is directly connected with the fixed cost of production of a firm, which is independent of the evolution of output by definition. The consequent emergence of economies of scale and the consideration of irreversible fixed costs (sunk costs) as a strategic variable for market competition (barriers to entry) have led to the development of new theories in the fields of Law and Economics, International Trade or Industrial Organization.

Definition

This expression refers to those expenditures (private or public) directed to purchase inputs that remain in the production process over relatively long periods of time (typically, until complete depreciation) and which are independent of the level of output.

The concept along the years

Traditionally, in economics the term “fixed investment” refers to outlays directed to the acquisition

of tangible assets (i.e., physical capital, which is normally denoted by “K” in formal models). This is typically one of the two generic inputs (the other is labor) considered in the production function. In this category, it is usually included structures and equipment if our analysis is exclusively focused on firms (micro level) and also infrastructures if we refer to the gross fixed capital formation of a territory (macro level). The difference between gross and net values is depreciation. The term “investment” refers to the addition of new assets during a period of time: It is a “flow.” The overall quantity of this factor of production over total employment (stock of capital to labor ratio) as well as its quality (technology) are essential determinants of labor productivity and, then, of economic growth and social welfare. Therefore, fixed investment has a double influence on the economy: a short-term impact through the generation of additional demand and a long-term effect via the increase in potential output.

The essential meaning of the word “fixed” in this context is that it represents an amount of money directed to those components that remain in the production process over time, normally until they are amortized. That is, these inputs are not easily adaptable to the particular circumstances of the evolution of output and, as such, are considered independent on its volume. This is the reason why the concept of “fixed investment” is usually amplified to include other more specialized expenses directed to intangible assets such as high qualified labor, investment on R&D, the acquisition of particular knowledge about markets or consumers’ behavior, and advertising. In fact, there is a subtle distinction in the literature between “fixed costs” and “sunk costs” when referring to this kind of investment. The latter generally refer to outlays that are focused on very specific economic activities and, therefore, that are not susceptible of alternative uses. That is, “sunk costs” are fixed costs that usually occur only once and which are irreversible.

In sum, the cost of production of a firm is composed by those expenditures that are directly related to the level of production and which are called *variable costs* (typically, low qualified labor, energy, raw materials, etc.) and those

related to fixed investment called *fixed costs*. In economic models, when modeling the *cost function*, the marginal cost of production is denoted by “c” (and it is multiplied by the variable reflecting the level of output) and the fixed cost of production is denoted by “F.” The relative weight of fixed costs compared to variable costs in the cost function of firms is generally considered as one of the key determinants of market structure. In fact, in the presence of fixed cost and constant marginal cost, the average (or unitary) cost of production is continuously decreasing as the level of output increases, a circumstance which provides advantage to larger firms over smaller ones thus leading to the appearance of imperfect competition. This occurs more likely in those sectors which require relatively higher amounts of fixed investment in the production process. These internal economies of scale are present in industries such as chemical, machinery, telecommunications, energy, vehicles, iron, and steel, etc.

The decision to invest in *permanent* assets (tangible or intangible) must be the result of an optimization problem, as it is the norm in economics. In this sense, there are two well-known analytical methods in order to choose the most appropriate project. The first one is the so-called net present value (NPV). The NPV of an investment is defined as the discounted value of the cash flows (profits plus amortizations) generated for the project over time. That is, the expected cash flow obtained from the investment in a given year in the future must be converted to present value using a discount factor. The summation of the corresponding amounts for the foreseeable number of years of life of the project has to be compared with the initial (fixed) investment. Those projects with positive NPV are susceptible to be accepted and the preferable will be the one with the highest NPV. The other method of evaluation of investment projects is the so-called internal rate of return (IRR). This is defined as the discount rate that makes the NPV of a project be equal to zero. Those projects with rates of return higher than the alternative in financial markets (typically, the interest rate of the riskless asset) are acceptable, and the best will be the one with the highest rate of return. This explains why when central banks

increase the interest rates of reference in the economy, the expected outcome is a reduction of capital formation by firms (private investment): Under these circumstances the number of profitable projects decreases. When we analyze public projects of investment (essentially, infrastructures) the approach is basically the same and it is called *cost-benefit analysis* (CBA). The main difference with private projects is that public managers have to take into account social costs and benefits. In this case, the issue is how to assign the corresponding money value. As before, those projects with the discounted present value of profits higher than the discounted present value of costs are potentially eligible.

The aforementioned economic tools of analysis can be useful in the ambit of law and economics. The existence of required initial fixed investment in business activities which are the result of a contractual relationship between parties can be studied under this perspective. One example is the franchise contract (see García-Herrera and Llorca-Vivero (2010)) in which the franchisor imposes to the franchisee not only the initial fixed investment (with the proper characteristic of *sunk cost*) in order to maintain the standard quality of the network but also other relevant variables such as resale prices. In this context, contract duration is going to be an essential element of adjustment to the equilibrium (for a general analysis about duration contracts, see also Guriev and Kvassov (2005)). Therefore, in order to reach the equilibrium, a positive correlation should be observed between the amount of the compulsory fixed investment and the duration of the franchise contract conditioned to other variables which are specific to the industry or to the business nature (i.e., price-cost margins, experience).

The consideration of the existence of fixed costs in production has led to the development of new theories in some branches of economics. For instance, the traditional trade theory was only capable to explain interindustry trade, that is, international trade that takes place in different industries among countries. This occurs because countries differ on technology (Ricardo's theory) or resources' endowment (Heckscher-Ohlin

theorem). Or, in other words, countries trade because they have comparative advantage in different types of goods (industries). However, the fact that the majority of trade among developed countries, which are similar in these two characteristics (technology and resources), is of an intraindustrial nature (trade of different varieties within the same industry) leads to the necessity of developing a new paradigm. The "new trade theory," formulated by Krugman (1979, 1980), centers the analysis in the existence of internal scale economies and product differentiation. In a monopolistic competition model, in which international trade is a way of expansion in market size, consumers have access to a higher number of varieties in a given industry at a lower price. This benefits obtained from world trade occur because firms are able to exploit economies of scale by means of output' expansion given the existence of fixed costs in production. That is to say, each country specializes in a reduced range of varieties. Obviously, the number of varieties in equilibrium is lower than the summation of existent varieties within countries in autarky but higher than the number of varieties consumers have at their disposal in the respective countries when no trade occurs.

More recently, the consideration of the existence of "sunk cost" as barrier to entry in international markets has led to further developments in modeling international trade. These "entry cost" are those required to profitable sales in foreign markets such as acquisition of knowledge about consumers' tastes or regulations (technical barriers), advertising, and the establishment of distribution channels. The theoretical and empirical models considering these sunk entry cost are known as the "new-new trade theory." This expression is normally used by reference to the influent Melitz (2003) article although some other authors previously emphasized the role of sunk cost in exporting as, for instance, Baldwin and Krugman (1989) or Roberts and Tybout (1997). Melitz (2003) notes, in a model with heterogeneous firms, than only the more productive ones are able to enter into export markets, giving an explanation to the observed pattern that just

a small fraction of domestic firms become exporters, a characteristic which is common across countries. The reason is that the fixed investment necessary to enter into foreign markets acts as a minimum threshold to be surpassed. Only those firms with expected net profits from exporting greater than this threshold will become exporters. In this sense, a theoretical and empirical distinction is made between the extensive margin of trade (which makes reference to the number of exporters) and the intensive margin of trade (which focuses in the volume of exports of these exporters). This line of research has demonstrated (see, for instance, Dixit (1989)) that the existence of sunk cost (for entry or exit) generates hysteresis in exporting, that is, prior experience is a determinant factor for current participation in exports markets. However, it seems that these fixed investments that generate such sunk costs rapidly depreciate after firm's entry and, therefore, are irrecoverable in the event of firm exit.

In a similar manner, irreversible fixed investment (sunk cost) has revealed as a strategic variable for firms' competition in the recent industrial organization theory. John Sutton (1991), in a work which encapsulates previous research (i.e., Shaked and Sutton (1983, 1987)) obtains relevant conclusions about market structure making a distinction between *exogenous* and *endogenous sunk cost*. In this context, the acquisition of a single plant of minimum efficient scale is considered as an *exogenous sunk cost* for firms given that the achievement of scale economies is conditioned by the existing technology. Decision variables for firms as advertising and R&D outlays (among other possibilities) are *endogenous sunk costs*, whose effect is the increase in consumers' willingness-to-pay (in Sutton's words) for the firm's product. The author demonstrates that, under the presence of *endogenous sunk costs*, the different industries will present a lower bound for market concentration, which is not affected by the increase in demand. This result is valid under very general assumptions about the nature of oligopoly models (number of products offered, type of price competition, etc.). This fact justifies why a high level of concentration persists in some industries

and it contradicts the previous general belief in the sense that market concentration indefinitely declines as the size of the markets increases, leaving this outcome as a special case in which *endogenous sunk costs* are nil. In a similar manner, an incumbent firm can preempt entry of potential competitors by investing in "sunk costs" such as advertising. This action will reduce the expected profits of these firms avoiding their entrance.

Food Safety

Christophe Charlier

Department of Economics, Université Côte d'Azur, CNRS, GREDEG, Nice, France

Abstract

Food safety is a quality of food. Its originality is to be implemented through a mix of public regulations and private safety control schemes. These measures can interfere with free trade of food, especially when a country wishes to reach a food safety level higher than the level ensured by international food safety standards. Different important dispute rulings in this area have created jurisprudence and an important debate on the WTO SPS Agreement.

Definition

Food safety is a quality attribute of food supplied to consumers. Food safety covers the hygiene of foodstuffs, and the public regulations as well as the private measures implemented in supply chains to reach food innocuousness.

In the wake of food-borne disease crises, food safety has emerged as an important focus for public authorities and agri-food supply chains operators. Viewed by economist as a market failure, food safety requires public policies. Regulations address the food safety issue mainly with a combination of mandatory sanitary standards, liability regimes where the achievement of a sanitary goal is left to the discretion of food operators, and specific food operators' responsibilities. This situation has been considered as a determinant for the rise of food safety private standards. Food safety standards can be constraining for international trade, creating disputes ruled under the SPS Agreement. The different rulings of the WTO Panel and the Appellate Body have created jurisprudence and an important debate on this WTO Agreement.

Introduction

Food-borne diseases crises have made food safety a focus for public authorities and agri-food supply chains operators. Examples are numerous and include bovine spongiform encephalopathy in the 1990s, the 2011 European E coli outbreak, the 2008 Chinese melamine crisis, the numerous contaminations of food with dioxin, etc. Negligence, pollution, modification of production patterns, and diversification of supply sources for raw materials have been pointed out as different reasons for these episodes.

Economists conceive food safety disorder as a market failure (Antle 1996). Food safety is a quality characteristic that cannot be discovered by consumers before purchase. In such a situation, free market conditions cannot guarantee that consumers find the safety level they are paying for. Suppliers' reputation (especially in case of large firms) and private certification have been, respectively, considered as possible motive and way to alleviate this information shortcoming. However, the importance of food-borne diseases and the fact that food safety cannot be provided to consumers without cooperative efforts of many independent operators along the food chains (producers, processors, and distributors) clearly show the need for regulation on efficiency grounds. Two important characteristics follow. First, food safety is implemented through a mix of public regulations and private safety control schemes where the former can be considered as minimal regulatory standards. Second, even if capture of the regulator by economic interest groups should not be discarded, the necessity to regulate and the determination of the socially desirable level of food safety are based on health standards with little space for cost-benefit consideration.

All these measures taken in a risk management perspective can interfere with international trade of food. In some cases a food safety standard may be qualified as nontariff barriers to trade. Therefore, compatibility of food safety public regulations and private measures with international rules of the World Trade Organization (WTO) Sanitary and Phytosanitary (SPS) Agreement is to be sought. The SPS Agreement does not specify an

exclusive sanitary regulation mode and refers to the Codex Alimentarius (Codex) as the relevant standard-setting institution. However, observance of its principles and of the guidelines of the Codex has created a general framework for sanitary regulation organized around three main areas (see Jackson and Jansen 2010 for a discussion): risk assessment, risk management, and risk communication. The risk assessment stage requires that any sanitary regulation be justified by a risk evaluation. The risk management stage demands that food safety standards should be taken with reference to an acceptable level of risk and should be proportionate to this level of risk. Finally, the risk communication stage requires the delivery of information about the risk and the measures undertaken to manage it to the interested parties.

Food Safety Regulations

The regulation addresses the food safety issue mainly with a combination of “command and control” regulatory tools and liability regimes (Henson and Caswell 1999). With command and control regulations, authorities enact mandatory sanitary standards, conceived as minimal quality standards, and examine their good implementation. Banning products considered as dangerous is an extreme form of this kind of regulation. By contrast, liability is a more incentive approach: authorities only fix a sanitary goal, its achievement being left to the discretion of food operators.

Command and Control Regulations

Regulatory tools in the field of food safety are various. Some directly address the sanitary risks looking at the production processes or at the quality of the output. The Hazard Analysis Critical Control Points (HACCP) method is one of these. It requires controls at certain points in the production process previously defined as the most critical for sanitary risks. Food operators from the European Union (EU), for example, are asked to observe “relevant hygiene requirements” set by the Regulation (EC) No. 852/2004, among which procedures based on the HACCP principles are present. Maximum Residue Limits (MRLs)

for pesticides is another example, where a quality standard expressed in terms of a maximum presence of pesticide in products has to be met. In the EU, for example, the use of MRLs for pesticides is required for fresh products of plant and animal origin by the Regulation (EC) No. 396/2005.

Some other regulatory tools address information disclosure rather than intrinsic production processes’ or food’s sanitary risk. Two complementary requirements can be met here. The first one is product labeling. Product labeling is intended to fill the information gap on the sanitary quality of food. It focuses on the foodstuffs’ content, declaring the presence of an allowed component which is however suspected by consumers to be risky (GMO, meat geographical origin, etc.), or which is risky for certain kind of consumers (possible allergic reactions to a component, for example). The second regulatory tool is traceability. Traceability is defined as the ability to identify and trace the history and location of a product. It does not signal food safety but is considered as a risk management tool permitting accurate withdrawals of products from the food supply chain in case of a sanitary risk occurrence. Traceability systems can be different according to three dimensions (Golan et al. 2004): breadth (the amount of information delivered), depth (how far back information record is made), and precision (the tracking unit used). The Regulation (EC) No. 178/2002, for example, demands that all input to the food production process should be tracked, requiring operators to be able to identify “the business from which the food, feed, animal or substance that may be incorporated into food or feed has been supplied.” Breadth and depth of such a system are therefore maximal, but the precision is very weak since no requirement on batch formation appears. Charlier and Valceschini (2008) show that with these characteristics, the mandatory traceability alone can hardly reach the goal assigned by the regulation of a targeted withdrawal of products.

Liability and Operators’ Responsibility

Food operators may be held liable when a safety problem occurs and causes health damages to consumers. Liability is often qualified as an ex

post regulation since it does not involve *ex ante* mandatory standards but only the general goal of food safety to compel with. Liability is therefore intended to provide incentives to food operators to control food safety through private risk management. Two broad liability regimes can be distinguished. Under negligence rules, an operator is held liable only if a fault is proven (due care to safety issue has not been developed). With strict liability, negligence does not have to be demonstrated. An important part of law and economics literature initiated by Shavell (1987) investigates the compared incentive properties of these two regimes. In a food supply chain composed of many operators, distributors pay special attention to liability since they are in a direct relation with final consumers. This situation creates strong incentives to control food safety not only at the distribution stage but also at upstream stages of the food chain.

Together with liability, food safety regulation stipulate food operators' responsibilities that may create incentives to develop private safety schemes in order to be able to meet the expected obligations. For example, Regulation (EC) No. 178/2002 defines food operators' responsibilities with regard to safety procedures required in case of a sanitary breakdown: food withdrawal, information delivery, and cooperation with public authorities are covered. Charlier and Valceschini (2008) argue that these responsibilities ask for "proactive" risk management practices requiring a capacity of food operators to trace their products more precisely than with mandatory traceability. The latter should therefore be considered as a minimum standard eventually completed with more stringent private practices.

In this perspective, liability has been considered as a good lever for "co-regulation" of food safety issues (Garcia Martinez et al. 2007) that appears when public regulation is coordinated with private initiatives. The relation between public regulation and private initiatives is more complex than a one-way relation (Henson 2008). Private initiatives make easier compliance with regulatory aims, but they also infuse public relations (traceability and HACCP are good examples).

Private Standards

The development of *ex ante* food safety regulations requiring operators' "proactive" risk management gives rise to food safety private standards (among other reasons like improving supply chain management and product differentiation when coupled with labeling) especially in Europe. These standards have the particularity to be more demanding than the mandatory ones in order to ensure enhanced levels of food safety and manage liability more effectively proving due diligence. Very often, retailers provide leadership in this area (GLOBAL GAP is an example). Their position at the junction between the food supply chain and the consumers, their size, and their strategy to develop reputation are complementary explanations. The performance of private standards insuring food safety, in situations where public regulations can hardly operate (because of the complexity of the food chains, their internationalization, etc.), is recognized (see Fagotto 2014 for a discussion).

This form of self-regulation poses potential problems. Private standards are often prerequisites for doing business decided downstream (retail stage) to be imposed upstream (in farms and along the supply chain), increasing therefore costs of upstream operators. A parallel with "soft" law can be done. Without having any legal character, private standards have legal-like practical effects (Henson 2008). Furthermore, multiple private standards can be socially costly so that harmonization should be promoted (see the Global Food Safety Initiative). Finally, as seen in the next section, private standards for food safety can be puzzling for international trade.

Food Safety and International Trade

Globalization of the food supply chains in a context where food safety standards are not harmonized makes necessary the control of risks at the borders. When the national standards implemented are recognized by the Codex, they cannot be considered as barriers to trade. However, product rejection and withdrawal carried out in these circumstances are costly. The 2013 "Rapid Alert

System for Food and Feed Report” of the EU shows that fresh products from developing countries are mainly concerned. This observation gives rationale for technical and financial assistance of developing countries to ensure their participation to the international trade of food and feed products (Unnevehr 2007).

National food safety standards can be more demanding than the Codex’s ones. This situation occurs when a country wishes to reach a food safety level higher than the level ensured by international food safety standards. These national food safety standards can be constraining for international trade and considered by other countries as barriers to trade. The disagreement arising in such circumstances over the legality of the national standards is ruled under the SPS Agreement principles. These principles and their interpretation made by different WTO Panels and the Appellate Body allow a country to choose a food safety standard higher than the corresponding international one. But they also require a proper risk assessment in order to demonstrate the need for such a standard. The latter should also be proportionate to the level of risk, in order to avoid being more constraining for trade than necessary. The primacy given to scientific justification by the SPS Agreement is more demanding than the traditional nondiscrimination GATT principle. This raises an important debate on the SPS Agreement and the weight we should give to other criteria such as collective preferences, or cost-benefit analysis (Trebilcock and Soloway 2002).

The most difficult situation arises when the risk is not firmly asserted (i.e., where only a presumption of risk is furnished), presenting the food safety standards as a “precautionary” measure. The ruling of emblematic SPS cases like *EC – Hormones* and *EC – Approval and Marketing of Biotech Products* shows that precautionary SPS measures cannot override the risk assessment requirement. Even if incomplete, a risk assessment has to be done. The SPS measure decided in such a case must be provisional and reevaluated with a “more objective” risk assessment “within a reasonable period of time.”

An original situation arises with private standards. In 2005, St. Vincent and the Grenadines

complained at the WTO SPS Committee that EUREPGAP’s SPS exigencies were stricter than the relevant regulatory ones. This launches a debate on whether private standards are more trade-diverting and trade-reducing than public ones (Henson 2008, Hobbs 2010) and on whether the WTO has jurisdiction over private standards. Trade diversion is feared because of compliance costs that can be too high for developing countries, thus favoring suppliers from countries with higher public standards. Trade-reducing or trade-enhancing property of food safety private standards largely depends on the degree of specificity of the investments required (and therefore on the harmonization of the different private standards). The SPS Agreement addresses governments’ regulations. However, its Article 13 requires members to ensure that private entities implementing SPS measures comply with the Agreement. Private standards are therefore puzzling for international commercial trade and are one of the subjects currently debated in the SPS Committee. This debate might be long. In March 2014, countries participating to the SPS Committee still disagreed on the definition to give to private standards.

Forensic Science

Marie-Helen Maras¹ and Michelle D. Miranda²

¹John Jay College of Criminal Justice, City University of New York, New York, NY, USA

²Farmingdale State College State, University of New York, Farmingdale, NY, USA

Abstract

Forensic science applies natural, physical, and social sciences to resolve legal matters. The term forensics has been attached to many different fields: economics, anthropology, dentistry, pathology, toxicology, entomology, psychology, accounting, engineering, and computer forensics. Forensic evidence is gathered, examined, evaluated, interpreted, and presented to make sense of an event and provide investigatory leads. Various classification schemes exist for forensic evidence, with some forms of evidence falling under more than one scheme. Rules of evidence differ between

jurisdictions, even between countries that share similar legal traditions. This makes the sharing of evidence between countries particularly problematic, at times rendering this evidence inadmissible in national courts. Several measures have been proposed and organizations created to strengthen forensic science and promote best practices for practitioners, researchers, and academicians in the field.

Definition

Forensic science involves the application of the natural, physical, and social sciences to matters of law.

Introduction

Forensic science refers to the application of natural, physical, and social sciences to matters of the law. Most forensic scientists hold that investigation begins at the scene, regardless of their associated field. The proper investigation, collection, and preservation of evidence are essential for fact-finding and for ensuring proper evaluation and interpretation of the evidence, whether the evidence is bloodstains, human remains, hard drives, ledgers, and files or medical records.

Scene investigations are concerned with the documentation, preservation, and evaluation of a location in which a criminal act may have occurred and any associated evidence within the location for the purpose of reconstructing events using the scientific method. The proper documentation of a scene and the subsequent collection, packaging, and storage of evidence are paramount. Evidence must be collected in such a manner to maintain its integrity and prevent loss, contamination, or deleterious change. Maintenance of the chain of custody of the evidence from the scene to the laboratory or a storage facility is critical. A chain of custody refers to the process whereby investigators preserve evidence throughout the life of a case. It includes information about: who collected the evidence, the manner in which the evidence was collected, and all individuals who took possession

of the evidence after its collection and the date and time which such possession took place.

Significant attention has been brought to the joint scientific and investigative nature of scene investigations. Proper crime scene investigation requires more than experience; it mandates analytical and creative thinking as well as the correct application of science and the scientific method. There is a growing movement toward a shift from solely experiential-based investigations to investigations that include scientific methodology and thinking. One critic of the experience-based approach lists the following pitfalls of limiting scene investigations to lay individuals and law enforcement personnel: lack of scientific supervision and oversight, lack of understanding of the scientific tools employed and technologies being used at the scene, and an overall lack of understanding of the application of the scientific method to develop hypotheses supported by the evidence (Schaler 2012). Another criticism is that some investigators (as well as attorneys) will draw conclusions and then obtain (or present) evidence to support their version of events while ignoring other types of evidence that do not support their version or seem to contradict their version (i.e., confirmation bias). Many advocates of the scientific-based approach believe that having scientists at the scene will minimize bias and allow for more objective interpretations and reconstructions of the events under investigation.

A scene reconstruction is the process of putting the pieces of an investigation together with the objective of reaching an understanding of a sequence of past events based on the physical evidence that has resulted from the event. The scientific method approach is the basis for crime scene reconstructions, which includes a cycle of observation, conjecture, hypothesis, testing, and theory. The process of recognizing, identifying, individualizing, and evaluating physical evidence using forensic science methods to aid in reconstructions is known as criminalistics. Here, identification refers to a classification scheme in which items are assigned to categories containing similar features and given names. Objects are identified by comparing their class characteristics with those

of known standards or previously established criteria. Individualization is the demonstration that a particular sample is unique, even among members of the same class. Objects are individualized by their individual characteristics that are unique to that particular sample (De Forest et al. 1983). Other important concepts in criminalistics include the comparison of objects to establish common origin using either a direct physical fit method or by measuring a number of physical, optical, and chemical properties using chemistry, microscopy, spectroscopy, chromatography, as well as a variety of other analytical methods. Furthermore, in forensic science, exclusion can be as critical as inclusion. Being able to compare materials to determine origin may rule out potential suspects or scenarios.

Forensic Evidence

Forensic scientists examine firearms, toolmarks, controlled substances, deoxyribonucleic acid (DNA), fire debris, fingerprint and footwear patterns, and bloodstain patterns (to name a few). Forensic evidence is collected, processed, analyzed, interpreted, and presented to: provide information concerning the corpus delicti; reveal information about the modus operandi; link or rule out the connection of a suspect to a crime, crime scene, or victim; corroborate the statements of suspects, victims, and witnesses; identify the perpetrators and victims of crimes; and provide investigatory leads.

Evidence classification schemes include: physical evidence, transfer evidence, trace evidence, and pattern evidence. Physical evidence includes objects that meaningfully contribute to the understanding of a case (e.g., weapons, ammunition, and controlled substances). Transfer evidence refers to evidence which is exchanged between two objects as a result of contact. Edmond Locard had formulated this exchange principle, stating that objects and surfaces that come into contact will transfer material from one to another. Trace evidence is evidence that exists in sizes so small (i.e., dust, soil, hair, and fibers) that it can be transferred or exchanged between two surfaces

without being noticed. Pattern evidence refers to evidence in which its distribution can be interpreted to ascertain its method of deposition as compared to evidence undergoing similar phenomena. This type of evidence can include imprints, indentations, striations, and distribution patterns. Criminalistics is concerned with the analysis of trace and transfer evidence and can include, but is not limited to, pattern evidence (fingerprints, footwear, gunshot residue), physiological fluids (blood, semen), arson and explosive residues, drug identification, and questioned documents examination. Questioned documents examination includes the evaluation and comparison of handwriting, inks, paper, and mechanically produced documents, such as those from printers.

Alternate classification schemes for evidence include: direct evidence, circumstantial evidence, hearsay evidence, and testimonial evidence. Many of these terms can be used interchangeably for a given type or sample. Direct evidence refers to evidence that proves or establishes a fact. Circumstantial evidence is evidence that establishes a fact through inference. Hearsay evidence refers to an out-of-court statement that is introduced in court to prove or establish a fact. Depending on a country's rules of evidence, this type of evidence may or may not be admissible in court. Countries, such as the United States, have stipulated in what circumstances hearsay evidence may be admissible (U.S. Federal Rules of Evidence). Testimonial evidence refers to evidence given by a lay or expert witness under oath in a court of law.

Forensic scientists, specifically laboratory analysts and individuals that have testified as expert witnesses, have come under much scrutiny and have been the subject of criticism for a variety of reasons. Some of the criticisms of these laboratory analysts include: the lack of understanding of the science and technology behind their tests and instruments employed (making them more akin to technicians rather than scientists), pro-law enforcement and pro-prosecution tendencies (especially for those individuals working for labs directly affiliated with state, government, or law enforcement agencies), the tendency to testify beyond their knowledge or expertise, the

falsification of credentials, the lack of laboratory quality assurance policies or the misunderstanding or misapplication of the quality assurance practices in place, data falsification, overstating the value or weight of the evidence, and the misuse of statistics (Moenssens 1993).

Domestic rules of evidence stipulate the criteria used to determine the competency of eyewitnesses and experts to testify. Limits on the admissibility of purportedly scientific evidence also exist by requiring a judge to ensure that an expert's testimony is both valid and reliable (e.g., U.S. Federal Rules of Evidence).

Rules of Evidence

Domestic rules of evidence vary between countries. Rules of evidence dictate the type of information that can be collected from computers and related technologies. These rules also proscribe the ways in which evidence should be collected in order to ensure its admissibility in a court of law. In order for evidence to be admissible in court, it must first be authenticated. This evidence must also be collected in a manner that preserves it and ensures that it is not altered in any way. The key to authenticating evidence is the maintenance of the chain of custody.

Formal and informal information sharing mechanisms are used to facilitate cooperation between countries in criminal investigations. Formal information sharing mechanisms include multilateral agreements, bilateral agreements, and mutual legal assistance treaties between countries. The latter requires each party to the treaty to provide the other party with information and evidence about crimes included in the treaty. By contrast, informal sharing mechanisms involve direct cooperation between police agencies. However, the evidence retrieved through this mechanism may be rendered inadmissible in a court of law because the rules of evidence differ between jurisdictions (even those jurisdictions with similar legal traditions). As such, forensic evidence obtained from another country might not be accepted in another national court.

Branches of Forensic Science

There are several branches of forensic science including (but not limited to): forensic economics, forensic anthropology, forensic odontology, forensic pathology, forensic toxicology, forensic entomology, forensic psychology, forensic accounting, forensic engineering, and computer forensics. The field of forensic economics emerged when courts began allowing expert testimony by specialists in a variety of different fields. Forensic economics is a branch of forensic science that applies economic theories and methods to matters of law. Forensic economists do not investigate illicit activity; instead, they apply economic theories to understand incentives which underlie criminal acts. Originally, forensic economics applies the discipline of economics to the detection and quantification of harm caused by a particular behavior that is the subject of litigation (Zitzewitz 2012). Forensic economics has also been used in the detection of behavior that is essential to the functioning of the economy or that may harm the economy (Zitzewitz 2012).

Forensic anthropology is a branch of science that applies physical or biological anthropology to legal matters. Particularly, it is concerned with the identification of individuals based on skeletal remains. Experts in this field examine human remains in order to determine the cause of death and to ascertain the characteristics of the person's remains they are examining (e.g., gender, age, and height) by evaluating the bones and any antemortem, perimortem, and postmortem bone trauma. Forensic odontology, sometimes referred to as forensic dentistry, is a branch of science that applies dental knowledge to legal matters. It is concerned with the identification of individuals based on dental remains and individual dentition. Forensic odontologists may also evaluate bite mark evidence in the course of their forensic endeavors. Forensic pathology, also referred to as forensic medicine, is concerned with the investigation of sudden, unnatural, unexplained, or violent deaths. Forensic pathologists conduct autopsies to determine the cause, mechanism, and manner of an individual's death. Forensic toxicology is concerned with the recognition, analysis, and

evaluation of poisons and drugs in human tissues, organs, and bodily fluids. Forensic entomology is a branch of science that applies the study of insects to matters of law. Experts in this field are primarily used in death investigations, for example, to shed light on the time and cause of death. Specifically, the life cycle of insects is studied to provide investigatory leads and information about a crime.

Forensic psychology involves the study of law and psychology and the interrelationship between these two disciplines. The American Board of Forensic Psychology defines forensic psychology as "the application of the science and profession of psychology to questions and issues relating to law and the legal system." Bartol and Bartol (1987) "view forensic psychology broadly, as both (1) the research endeavor that examines aspects of human behavior directly related to the legal process; and (2) the professional practice of psychology within, or in consultation with, a legal system that embraces both civil and criminal law" (3). There is considerable disagreement about the nature and extent of activities and roles that fall under the domain of forensic psychology (DeMatteo et al. 2009).

Forensic accounting is a branch of forensic science that applies accounting principles and techniques to the investigation of illicit activities and analysis of financial data in legal proceedings. Forensic engineering is concerned with the investigation of mechanical and structural failures using the science of engineering to evaluate safety and liability. Lastly, computer (or digital) forensics "is a branch of forensic science that focuses on criminal procedure law and evidence as applied to computers and related devices" such as mobile phones, smartphones, portable media players (e.g., iPads, tablets, and iPods), and gaming consoles (Maras 2014, p. 29). Computer forensics involves the acquisition, identification, evaluation, and presentation of electronic evidence (i.e., information extracted from computers or other digital devices that can prove or disprove an illicit act or policy violation) for use in criminal, civil, or administrative proceedings. Electronic evidence is volatile and can easily be lost and manipulated. Maintaining a chain of custody is essential in the preservation and admissibility of electronic evidence.

Strengthening Forensic Science

Increased application of DNA evidence and improved practices and methodologies of crime scene investigations, evidence analysis, and quality assurance measures have resulted in many convictions being reviewed and subsequently overturned. The trend toward wrongful convictions has exposed limitations in forensic science methodologies as well as some forensic analysts. Increased scientific scrutiny, increased quality control within the laboratory, as well as increased professional standards for employment of scientists in the field of forensic science have contributed to improvements in the field, but have not completely ameliorated the lack of oversight apparent in forensic science. The Innocence Project (n.d.) lists unvalidated or improper forensic science (further subdivided into the absence of scientific standards, improper forensic testimony, forensic misconduct) as one of the most common contributing factors to wrongful convictions. According to the Innocence Project (n.d.), other contributing factors to wrongful convictions are eyewitness misidentification, false confessions/admissions, government misconduct (misconduct by law enforcement officials, prosecutorial misconduct), informants, and bad lawyering (inadequate or incompetent counsel).

Driven in part by the status of wrongful conviction in the United States, the National Academy of Sciences Report, *Strengthening Forensic Science in the United States: A Path Forward*, was drafted to address many of the problems plaguing forensic science (Committee on Identifying the Needs of the Forensic Sciences Community, 2009). This document addressed several challenges facing the forensic community, including: disparities in the forensic science community (standard operating procedures, resources, oversight); lack of mandatory standardization, certification, and accreditation; the scope and diversity of forensic science disciplines; problems relating to the interpretation of forensic evidence (such as the degree of scientific research and validity for the various disciplines); the need for research to establish limits; and measures of performance and the admission of forensic science evidence in litigation (concerning the scientific rigor of the

discipline and resultant interpretations as well as the qualification of the expert providing testimony). The report proposed thirteen (13) recommendations ranging from establishing best practices and a scientific foundation within all forensic science disciplines, accreditation of all forensic laboratories, certification of all forensic scientists, increased research to address the reliability and validity of the various forensic science disciplines (e.g., uncertainty measurements, effects of observer bias and human error, development of standardized and scientific techniques, technologies, and procedures) to the development of a code of ethics. Furthermore, organizations, such as the American Academy of Forensic Sciences, European Association of Forensic Sciences, European Network of Forensic Science Institutes, and the International Association of Forensic Sciences, have been created to improve the exchange of forensic science knowledge and best practices between practitioners, researchers, and academicians in the field of forensic science.

Franchise

Alicia García-Herrera

Valencia, Spain

Abstract

Since the second half of the twentieth century, the variations in the exchange system of goods and services have allowed the expansion of integrated distribution networks, based on franchise or other distribution agreements. Franchise offers specific benefits to the firms, reducing transaction costs. Manufacturers and suppliers may have access to new markets, raising capital, sharing risks and saving costs, but maintaining the control of the franchisees' behaviour through the terms of the contract. Franchising is also attractive to franchisees, because of the backing of a successful and recognized system and the ongoing support of the brand to the entrepreneur. However, certain practices, like resale maintenance or price discrimination, territorial restrictions or refusal to supply (among others) may restrict competition among firms by establishing barriers to entry, and consequently they have been controlled by antitrust law. In the internal relationship, the unequal allocation of rights, with the attribution of broad powers to franchisors, including termination at *will*, favours the opportunistic behaviour of both parties. The legal approach has considered the vulnerability of the franchisee and the unequal bargaining power between the parties by imposing pre-contractual disclosures rules and regulating the termination. In front of these views, economic analysis has criticised the state interventionism in franchising. Both perspectives, opposite, should be considered in order to have an adequate comprehension of the reality inherent to franchise contracts.

Synonyms

Franchising

Definition

Franchise is a successful system of business organization to market goods and services based in a contractual relationship between two legally independent parties, according to which one well-established business, the franchisor, in exchange for the pay of an initial sum, fees or periodic royalties, transfer or license to the other part, the franchisee, the right to use in a given area and during a period of time, their trademark, trade name, or another industrial and intellectual property rights, with the provision of commercial support and technical assistance.

Franchise as a Business Model

From a broad perspective, franchise can be defined as a contractual relationship involving two legally independent entrepreneurs with the goal of market goods or services in a given location during a specified or indefinite period of time. Using a narrow approach, franchise commonly refers to those agreements known as *business format franchise*. In this sense, the purpose of contract is the transmission by the franchisor of a successful and recognized business system, giving continuous provision of commercial and technical assistance to the franchisee. Subsequently, the franchisor must make available to the franchisee – through appropriate license agreements – all *intangible assets* that had led the company success (*good will*), like the brand name or another industrial and intellectual property rights as well as the *know-how*. The franchisee has obligations of confidentiality and no competition about franchisor's business methods, even after termination of the relationship. In exchange to join the network, the franchisee assumes the payment of an *up-front lump sum* or fixed initial *fee* and ulterior royalties, commissions, or percentages of retail sales. Given that his business opportunity is the distribution of the product or service under franchisor's techniques and knowledge, the franchisee may make highly specific investments to maintain the value and quality of the brand – thus, franchisors must guarantee a reasonable length of the contract. The contract clauses, standardized, attribute to the franchisor

wide powers of monitoring. The franchisor controls the supply, distribution, and the resale of goods or services, although he is obligated to provide equal treatment to all franchisees. He imposes conditions about characteristics of the franchised outlet and staff training because the network has to be homogeneous and uniform. By recommending resale prices and coordinating franchise advertising and promotional activities, the franchisor is involved in the distribution process.

Business format franchise must be differentiated from *product distribution franchise*, which is basically focused in the reselling of franchisor's brand products (often soft drinks, automobiles, and gasoline), frequently with the allocation to the franchisee of exclusive agreements about supplies and area (not necessarily present in business format franchise). In this case, the franchisor habitually does not provide to franchisees an entire system of business. The degree of integration is apparently minor than in the business format franchise. However, both types of distribution agreements can be combined in practice. The *business format franchise* must also be differentiated from *selective distribution*, which is characterized by the selection of resellers considering criteria directly related with the specialties of luxury markets or complex technology products.

The existing literature refers the origin of modern franchise to the USA, even though etymologically the term comes from the Old French word *Franc* (*free*) and its derivation *francher* or *affranchir*. The medieval franchise consisted on privileges granted by kings and lords to their vassals to obtain licenses about trade, fishing or forestry rights, exemptions about taxes or customs, although it was also associated to the statutes of the *villas francas*, released of manor or vassalage. In the sense of concession or privilege, the term franchise still remains in government grants and in the field of sports. Despite this, the franchise, as we know it today, arises in the late nineteenth century as a distribution method used by manufactures to avoid the application of the *Sherman Act*, which impeded to manufactures the resale to final costumers. The great boom of the franchise occurs after Second World War, with the expansion of the *business format franchise*

(s. Martinek 1992, Martinek, Semler & Flohr 2015).

Nowadays, franchise networks represent almost a third of retailing in the USA. According to the *Franchise Business Economic Outlook for 2014*, a report prepared by the *International Franchise Association (IFA) Educational Foundation*, around 3.5 % of the US GDP corresponds to franchise business (a total of \$ 472 billions). This method of distribution is especially relevant to small and medium sized firms. In Europe, the statistics of the *European Franchise Federation* show that franchise is also growing, although the impact of franchise is still minimal comparing to USA or other countries, as Japan, Canada, and Australia. New technologies as the *Internet* – via e-commerce – may be a likely way of development of franchise.

Franchise contracts have interested both lawyers and economists. Initial economic works showed that franchise was an efficient method for reducing monitoring and agency costs (Caves and Murphy 1976; s. also model of Rubin, 1978). The agency theory explains that franchising is an optimal business decision when the cost of monitoring is high, as in the case of dispersed units located far from the franchisor (Mathewson and Winter 1985; Brickley and Dark 1987; Shane 1996, 1998, among others).

But, in the business relationship incentive and interest conflicts may arise, reducing the efficiency of the franchise contract. A franchise is a long term and *relational contract*, in which certain conditions are implicit, due to the inability to predict at the outset all contingencies. This fact implies that both franchisors and franchisees must consider common interest, being reciprocally obligated to act in *good faith* (this being understood as a fair behavior and the prohibition of reciprocal opportunism). But, both franchisors and franchisees have also incentives to take advantage of the loopholes and uncertainties of the written contract in their own benefit. From the agency theory perspective, franchisors must protect the value of their trademarks from the problems of *adverse selection* (the franchisor cannot ensure that the franchisee is able to reach the purpose of the contract) and *moral hazard*. Due to vertical and horizontal externalities, the franchisee

has a tendency to practices like double marginalization, underinvestment, and internal *free riding*. The franchisee may also be worried about the franchisor *holdup*. In the relationship, he acts as a passive investor. Through *encroachment* (invasion of the area of protection or the franchisee's territory) or simply by exercising their right to cancel or not renovate *at will*, franchisors may appropriate profits of efficient franchisees, such as *sunk cost* and the local goodwill built by their efforts.

The legal approach has considered the vulnerability of franchisees, in general less sophisticated and with a lower bargaining power than franchisors – thus, the franchise contract may be subject both to laws regarding unfair terms and to those prohibiting discrimination (antitrust law and contract law). The imbalance between the parties has justified the global tendency to the regulation of franchise agreements or, in the absence of law, designing mechanisms of court enforcement (based on *Common Law*). Complementary, different associations have developed *Codes of Ethics* for franchising.

The first laws about franchise arise in the USA. At the federal level, the Federal Trade Commission (FTC) Rule 1979, amended in 2007, governs presale disclosure obligation and registration. The government also regulates the termination of the relationship in specific areas, as automobile (Federal Automotive Dealer Franchise Act, FADFA 1956) and petroleum sectors (Petroleum Marketing Practices Act, PMPA 1978). From 1971 to 1992, a third part of states enacted relationship laws about franchise and automobile dealers. Franchise relationship laws impose the performance of the contract in *good faith*, encouraging the stability of the relationship, prohibiting *encroachment*, and establishing restrictions about termination. The termination or not renovation of the contract is based on various formal requirements (notification, notice, cure period) and on allegation of *good cause*. This legislation has influenced other legal systems and international law (s. the draft UNIDROIT *Model Franchise Disclosure Law*). Many countries in Asia, Latin America, and Canada regulate franchise to a greater or lesser extent. In general terms, franchise

has been not “*encoded*” in Europe, but in the last decade the tendency is changing. The Italian law is a good example. France, Belgium and Spain have enacted laws about disclosure obligations of franchisor and registration. The *Spanish Draft Commercial Code* establishes also parameters about the duration of franchise and distribution agreements (*reasonability*), the termination of the relationship, and the compensation of the franchisee (articles 543–18 to 543–249).

Over the last decades, starting from agency theory, the economic literature has tried to explain the economics of franchise contracts. A great number of works focus especially in the study of monetary clauses (*royalty rate* and *initial franchise fee*). The monetary clauses ensure a continuous flow of rents that benefits both franchisors and franchisees and offer incentives in order to control *double-sided moral hazard* (starting by Rubin, 1978, s. for a model Bhattacharya and Lafontaine 1995 and later empirical works that support this model, Lafontaine and Shaw 1999). A complementary approach has showed that franchise contracts themselves are designed to solve the problem of postcontractual opportunistic behavior as well as incentive conflicts through mechanisms of *self-enforcement* (Brickley et al. 1991; Mathewson and Winter 1994; Klein 1995; Dnes 1993, 1996). The disciplinary powers of the franchisor and, if required, the termination of the relationship can constitute a very efficient *hostage* to assure the optimal performance. The end of the relationship supposes to the franchisee the loss of the ongoing rents and future profits and additionally, the recovery of specific investments can be difficult. The economic literature considers that the risk of opportunistic behavior by the franchisee is higher than the risk of the franchisor *holdup*. Theory suggests that franchisors would tend to throw out of the network less efficient franchisees (Blair and Lafontaine 2010) and have no incentives to the appropriation of resources – they are interested in maintaining the brand prestige, which could be damaged by litigations derived of termination, thus generating the image of “*hard network*.” This approach explains the structure of franchise contracts and justifies the asymmetrical allocation of rights in favor of

franchisors, with the power of termination *at will* (s. empirical work of Arruñada et al. 2001, 2005, 2009, about automobile dealing agreements).

Most recent economic works have considered that, in long-term contracts, optimal contract duration can be a mechanism to reduce incentive conflicts and to avoid the problem of underinvestment (Guriev and Kvasov 2005). Given that the literature traditionally has assumed that initial investments are a key factor for the expected length of the franchise agreements (Joskow 1987; Brickley et al. 2006), a theoretical model to determine optimal duration of franchise is developed in García-Herrera and Llorca Vivero 2010 and empirically tested.

The economic analysis of the franchise contract, supported by empirical works, suggests that in general both *Franchise termination laws* – and even, those that protect franchisees from unfair treatment and discrimination – have no justification, inducing to a reduction in the use of franchise (s. Smith 1982; Beales and Muris 1995; Blass and Carlton 2001, about gasoline retailing; most recently, about automobile industry Arruñada et al. 2009; Lafontaine and Scott Morton 2010; Zanarone 2009; Zanerone 2012, about rigidity to adapt the contract). But the impact of franchise relationship laws is not homogenous because of its differences (Klick et al. 2008). Moreover, given that the opportunistic behavior of franchisors is not entirely compensated by the contractual engineering of the franchise, complementary legal, court, and extralegal enforcement mechanisms can be justified under certain conditions (s. Dnes 2009).

Vertical restraints associated to franchise contracts have been also analyzed from the *antitrust law* perspective. Some practices like the resale price maintenance or price discrimination, territorial restriction, tied-in sales, or the refusal to supply may breach antitrust laws. The economic analysis has justified vertical restraints associated to franchise contracts because of their efficiencies and benefits (Klein 1995; Rey and Stiglitz 1995; Mathewson and Winter 1994; Lafontaine and Slade 2007 among others). Since the eighties, the European Commission has enacted block exemption regulations (BER) about distribution and dealership agreements,

complemented by guidelines, and after the case *Pronuptia*, also about franchise. These rules, unified nowadays – excluding automobile sector – have been criticized and successively amended (the last modification was in 2010 (Commission Regulation (EU) No. 330/2010 of 20 April 2010 on the Application of Article 101(3) of the Treaty on the Functioning of the European Union to Categories of Vertical Agreements and Concerted Practices [2010] OJ L102/1-7; Commission Regulation (EU) No. 461/2010 of 27 May 2010 on the application of Article 101(3) of the Treaty on the Functioning of the European Union to categories of vertical agreements and concerted practices in the motor vehicle sector [2010] OJ L129/52-5; Commission Notice, Supplementary Guidelines on Vertical Restraints in Agreements for the Sale and Repair of Motor Vehicles and for the Distribution of Spare Parts for Motor Vehicles [2010] OJ C138/16-27.7.), reflecting the changes in distribution, as *e-commerce* and relaxing policies about passive sales and resale price maintenance).

Summary and Future Directions

Economic analysis has explained the business decision about franchise and the economics of franchise contracts, justifying the asymmetrical allocation of rights and vertical restraints associated. The empirical works have also demonstrated in general the negative effect of franchise relationship laws over the business decision about market goods or services through franchise. However, these generic results require qualifications and more empirical work should be necessary. The current tendency in Europe, as before in USA, is to ensure the stability of the contracts and their equilibrium by mechanism of legal and court enforcement, providing certainty and incentives to entrepreneurs to invest in franchise. In the reduction of litigations derived from under-performance, renegotiation or termination of the contract, it should be studied the complementary role of mediation, negotiation or arbitration clauses. EU competition rules for franchising agreements should probably be amended in the future to reflect the changes in distribution caused by the Internet phenomenon.

Frisking

Matt E. Ryan
Department of Economics, Duquesne University,
Pittsburgh, PA, USA

Definition

Established by the Supreme Court in *Terry v. Ohio* (1968), police officers may perform a frisk – a limited search of a civilian’s outer clothing in pursuit of weapons or nonthreatening contraband – when they determine suspicious activity is afoot or otherwise feel threatened.

Legal Framework

The legal framework surrounding frisking stems from *Terry v. Ohio* (1968):

We merely hold today that where a police officer observes unusual conduct which leads him reasonably to conclude in light of his experience that criminal activity may be afoot and that the persons with whom he is dealing may be armed and presently dangerous, where in the course of investigating this behavior he identifies himself as a policeman and makes reasonable inquiries, and where nothing in the initial stages of the encounter serves to dispel his reasonable fear for his own or others’ safety, he is entitled for the protection of himself and others in the area to conduct a carefully limited search of the outer clothing of such persons in an attempt to discover weapons which might be used to assault him.

Terry concerns only weapons; procedures for stops involving contraband come from *Minnesota v. Dickerson* (1993):

The question presented today is whether police officers may seize nonthreatening contraband detected during a protective patdown search of the sort permitted by *Terry*. We think the answer is

clearly that they may, so long as the officer’s search stays within the bounds marked by *Terry*.

Arizona v. Johnson (2009) extends *Terry* to traffic stops by citing *Berkemer v. McCarty* (1984), which notes that “[m]ost traffic stops resemble, in duration and atmosphere, the kind of brief detention authorized in *Terry*.” As such, these United States Supreme Court cases form the foundation of the role of the police officers’ permissible behavior concerning frisks in the two arenas generally examined empirically.

Stop-and-Frisk

“Stop-and-frisk” programs constitute stopping, questioning, and frisking pedestrians. In theory, stop-and-frisk programs are discriminatory if implemented unevenly across groups – be it race, ethnicity, gender, age, or any other margin. However, finding the appropriate null hypothesis, or benchmark, to statistically test these claims can be difficult. For instance, consider a hypothetical police department that implements a stop-and-frisk program; in doing so, they perform an unequal number of frisks across races. This outcome alone is not evidence of discrimination as the proper comparison must be made in order to determine any deviation from a no-bias level. City population figures could provide a benchmark but requires the assumption that criminal activity within the city is in proportion to population across races. Proportion of crimes committed across races could be a benchmark yet requires an assumption of criminal activity across races being proportional to crime committed. Moreover, discrepancies in frisking across races must control for discrepancies in exposure to policing across races as well. For a healthy discussion of benchmarking issues, see Ridgeway (2007).

Nevertheless, many studies investigate stop-and-frisk programs. Whether race-based discrimination exists in the implementation of New York City’s stop-and-frisk program is a particularly popular subject, with most studies finding some sort of inequality along race lines. Ridgeway (2007) finds that nonwhites received slightly more frequent

frisks, though differences in raw statistics overstate racial disparities. Gelman et al. (2007) find that black and Hispanics are stopped twice as frequently as whites, though arrested less frequently. Significant racial disparities exist in New York City pertaining to implementation of marijuana enforcement across both stops and arrests (Geller and Fagan 2010). Friedman (2015) finds African-American suspects less likely to be in possession of contraband as compared to white suspects. Goel et al. (2016) show that blacks and Hispanics are disproportionately stopped in scenarios with a low probability of a successful frisk – i.e., discovering weapons or contraband. Fryer (2016) notes that black and Hispanics are more likely to have an interaction with police involving force. Conversely, Coviello and Persico (2015) generate a unique measure of racial bias and find that race disparities in police pressure across precincts are not correlated with this measure. New York's stop-and-frisk program likely received considerable scholarly attention – at least in part – due to the sheer volume of stops performed; the database utilized by Fryer (2016) contains nearly five million stops, with annual stops between 2003 and 2013 numbering well into the hundreds of thousands. A US district court ruling in 2013, however, determined the implementation of the New York stop-and-frisk program to be unconstitutional (the program itself was not deemed to be unconstitutional), and consequently the number of stops performed annually by the New York City Police Department has dropped by over 90%.

Pertaining to the broad practice of frisking, Persico and Todd (2006) show that officers administer searches so as to maximize the number of successful searches. Antonovics and Knight (2009) note that searches are more likely to occur when the races of the officer and the searched differ; several additional studies consider officer race in relation to suspect race; see Skogan and Frydl (2004), Brown and Frank (2006), Sklansky (2006), and Gilliard-Matthews et al. (2008). Further, Durlauf (2005) notes that there exists an equity/efficiency trade-off in racial profiling – namely, the inequity in racial profiling must be weighed against the reduction in crime rates should underlying cross-race

differences in illicit activity dictate such a relationship to exist.

Frisking and Traffic Stops

While stop-and-frisk programs concern officers' interaction with citizens "on the street," a number of studies have investigated frisking in the context of a traffic stop. Most find a similar racial component to frisking during traffic stops as with the above-discussed "on the street" stops. In an early study, however, Knowles et al. (2001) find no evidence of racially prejudiced search behavior against black Maryland motorists, instead finding a modicum of bias against white and Hispanic motorists. Examining a wide swath of Missouri municipalities, Rojek et al. (2004) show that black and Hispanic drivers are approximately twice as likely as white drivers to be searched once stopped. Schafer et al. (2006) find that black and Hispanic drivers are more likely to be searched in an anonymized Midwestern city. Rosenfeld et al. (2012) find that young black males are searched more frequently than young white males in St. Louis and that this gap disappears for drivers over the age of 30. Novak and Chamlin (2012) show that the search rate for white motorists in Kansas City increased as the percentage of blacks in a particular neighborhood increased; black motorists were not searched more frequently. Ritter (2013) finds evidence of implicit race discrimination in traffic stops performed in Minneapolis. In Rhode Island, Carroll and Gonzalez (2014) show that black drivers are more likely to be frisked than white drivers, conditional on the racial composition of the community in which the traffic stop takes place. In Pittsburgh, Ryan (2016) finds a black male to be up to 8% more likely to receive a frisk when compared to an equivalent white driver.

Definition

Frivolous lawsuits refer to cases that are brought by plaintiffs with the only objective to extract settlement offers from defendants. Whereas a wide literature questions the credibility of frivolous litigation, this phenomenon had significant policy implications by inspiring several legal reform acts designed to deter meritless claims. Indeed, the issue of frivolous suits may be important from a welfare perspective since such claims may consume substantial resources (due to litigation costs, judicial

congestion, etc.) and have negative distributive consequences (since a payment is made to a party who has no legal entitlement to recovery).

Introduction

Many scholars and policy makers have expressed concerns about frivolous suits. However, despite this broad concern, there is no consensus about how a frivolous case should be defined (Bone 1997; Spier 2007). A first approach defines frivolous suits as negative expected value suits, i.e., claims in which the expected award at trial (probability of winning times award in case of victory) is lower than the plaintiff's litigation costs. But as Bone notes, the problem with such definition is that cases with very high merits and high probability of winning would be considered as frivolous suits if the costs are very high too. According to a second definition, a frivolous suit is defined by its very small probability of success. But this definition implies that if a jury is biased toward a plaintiff, then even though the probability that the defendant be liable is very low, that suit would not be frivolous according to that definition, although most people would consider it is. A third definition is not based on the probability of success (which can be subjective) but on the plaintiff's belief that there is little or no chance that the defendant be liable.

Departing from these definitions, it appears that a frivolous plaintiff ("she") would rather drop her case rather than going to trial. However, the defendant ("he") may fear the prospect of incurring high litigation costs in case of trial or face uncertainty by ignoring whether the claim is frivolous or not (Katz 1990). In such situations, he could be prone to make a settlement offer to the plaintiff.

Empirical Evidence

Given the negative welfare implications of frivolous litigation (increase in the overall number of cases in courts, judicial congestion, litigation costs, unjustified transfers of wealth), frivolous

suits are frequently cited as a major cause of the civil judicial system's most serious ills, despite the very little reliable empirical data confirming the importance of this phenomenon. This is notably the case in the USA where the number of nuisance suits has been an often-voiced concern for decades. For example, in a reported survey of American jurors in cases in which firms and corporations were defendants, more than 80% of the jurors indicated that they agree/strongly agree with the statement according to which "there are far too many frivolous lawsuits today" (Polinsky and Rubinfeld 1993). In the same way, the society's perceptions of the tort system are highly influenced by anecdotes of specious claims, one of the most emblematic being the Mc Donald's coffee case (see *Liebeck v. Mc Donald's Restaurants*, Docket No D-202 CV-93-02419, 1995 WL360309, Bernalillo County, N.M. Dist. Ct. August 18, 1994). The concerns about the existence of frivolous litigation gave rise in the 1980s and the 1990s in the USA to several litigation reform acts designed to deter meritless suits. For instance, Rule 11 of the Federal Rules of Civil Procedure provides for the imposition of sanctions on individuals who present claims which are deemed to be frivolous.

Threat to Litigate and Credibility

P'ng (1983) highlights that even if a defendant is aware that the claim is frivolous, the fear to see the case going to trial anyway might lead him to make a settlement offer that would be lower than his trial costs. However, following the argument by Bebchuk (1988), the plaintiff's threat to litigate is not credible in such a situation and a settlement should not occur, lessening the plaintiff's incentives to file a frivolous case: Knowing that the plaintiff will be not incited to go to trial *ex post*, the defendant is not prone to settle *ex ante*. In this paper, Bebchuk highlights that a negative expected value suit can be filed only in the presence of uncertainty. Indeed, if the plaintiff has private information about the level of damage she suffered or about her expected litigation costs, then the defendant might not know that

the expected value of litigation to the plaintiff is negative, making the plaintiff's threat to litigate the claim credible (see also Katz 1990, who considers an asymmetric information framework).

Bebchuk (1996) considers litigation with two stages and litigation costs at each stage. A party can propose a settlement at each stage, which can be accepted or refused by the other one. In this model, even if the case has a global negative expected value, the claim may, depending on the last stage's litigation costs, become positive expected valued. The plaintiff would thus have a credible threat to go to trial at the stage of litigation and bring the defendant to make an offer. On the opposite side, Schwartz and Wickelgren (2009) challenge this result and argue that nuisance suits are not credible. Their result relies on the assumption that during litigation, both parties can make offers at any time and at no cost. This implies that the plaintiff would not be able to extract a settlement that is large enough to make the initial threat of filing credible. Other arguments against the credibility of frivolous suits rely on a possible strategy for defendants that would be to develop a reputation of refusing to settle (Bone 1997). Nevertheless, as noted by Hubbard (2014), the same argument can apply to the opposite reasoning since plaintiffs might also commit to a policy of refusing to be deterred (Farmer and Pecorino 1998; Chen 2006).

Public Regulation

Some policy instruments are considered in literature to deter frivolous suits by undermining the ability of plaintiffs to extract settlements. Polinsky and Rubinfeld (1993) analyze the sanctions that can be enforced to this end and highlight the conditions that these sanctions should fulfill. In particular, the sanctions would be more (respectively less) desirable when litigation costs due to their use are low (respectively high). Moreover, when sanctions are enforced, they should be set so as to deter frivolous plaintiffs and not so as to compensate non-frivolous defendants. Finally, they underline the fact that in order to avoid discouraging legitimate plaintiffs to sue because of mistakenly

imposed sanctions, the judgment awarded to a legitimate plaintiff should be raised, all by keeping the expected costs borne by the defendant constant.

The English fee-shifting rule, which requires the losing litigant to pay the litigation costs of the winning party, might be a second instrument to deter frivolous suits by discouraging low-probability-of-prevailing cases. Nevertheless, the effect of the English rule on the incentives to file frivolous claims is ambiguous. Bebchuk and Chang (1996) show that if the plaintiff could predict the trial outcome with certainty, then a frivolous suit should not occur under the English rule. However, such a claim may occur if the plaintiff cannot predict the trial outcome without error. Indeed, with small litigation costs, a frivolous plaintiff could file anyway because of a small but positive chance of victory. In the same way, consider a negative expected value case where the probability of winning is quite high but the damages are very small. As argued by Spier (2007), the English rule will encourage such a case by enhancing its value given that the plaintiff's litigation costs will be shifted to the defendant at trial. Farmer and Pecorino (1998) analyze frivolous suits in a repeated play setting in which a lawyer may develop a reputation for proceeding to trial with a frivolous suit when facing a refusal by the defendant of the plaintiff's pretrial offer. According to them, such a reputation is necessary to maintain a credible threat of trial in future periods, and the value of this future reputation generates the credibility to pursue a case to trial in the current period. In this context, the English rule would discourage frivolous suits since the defendant's willingness to pay to settle decreases in the percentage of litigation costs that can be shifted to the losing party in case of trial.

Finally, some scholars and commentators have argued that the American system of contingent fees, under which the attorney gets a share of the judgment if his client wins and nothing if he loses, may encourage frivolous claims and should therefore be prohibited. These arguments are based on the idea that a plaintiff's threat to litigate is higher with contingent fees because the lawyer is not paid in case of losing. Dana and Spier (1993) challenge this argument: When the plaintiff's

attorney has better information about the merits of the case than his client, then this latter is constrained to rely upon the lawyer's recommendation, given that the contingent fee arrangement will encourage this lawyer to pursue only cases with sufficiently high expected returns. In this context, the contingent fee regime should decrease the extent of frivolous litigation. Instead, under a fixed or an hourly fee, the lawyer would be incited to lead the plaintiff blindly into litigation regardless of the claim's merit.

Galbraith, John Kenneth

Alexandre Chirat
Triangle, Université Lumière Lyon II, Lyon,
France

Abstract

John Kenneth Galbraith was a post-Keynesian and an institutionalist economist. He is famous for having built an unconventional vision of American Capitalism in his postwar trilogy (1952b, 1958, 1967). His socioeconomic analysis deals with subjects such as theory of the firm, managerial revolution, public spending, theory of consumption, price control (1952a), financial crises (1955), power relationship (1983), and more generally with the dynamic of capitalist institutions.

Biography

“Ken” Galbraith (October 15, 1908–April 29, 2006), born in Ontario, was trained after the 1929 Great Crash and passed a Ph.D. at Berkeley in Agricultural Economics (Galbraith 1981). He moved to Harvard during the 1930s and spent a year in Cambridge among Keynes’ fellows (UK). During World War II, Galbraith led the Office for Price Administration. He also oversaw a committee for the evaluation of the effects of American bombings on the German War Economy.

Galbraith then made a journalist career at *Fortune Magazine*. At the political level, he was a leading figure, with his friend Arthur Schlesinger, of the *American for Democratic Action (ADA)* and a special adviser of Democratic candidates running for the Presidency. In 1958, he lamented the “private opulence and public squalor” in his best-seller *The Affluent Society* (1958). J.F. Kennedy named him Ambassador to India in 1961. This experience delayed the publication of his masterwork, *The New Industrial State*, which gave rise to several debates among economists. He spent the rest of his academic life struggling against neoclassical economics and its “conventional wisdom,” against the fact that economists tended to overlook real social issues in favor of purely analytical constructions and intellectual puzzle. For these reasons, John Kenneth Galbraith was one of the most renowned public intellectuals of postwar Anglo-Saxons societies. Indeed he always relied on public enlightenment and developed his ideas for large audiences. For instance, he took part in a TV series entitled *The Age of Uncertainty*, broadcast on the BBC during the 1970s, which aimed to get people acquainted with economic knowledge (Parker 2005).

Innovative and Original Aspects

In his work Galbraith has always insisted on the idea that power *de facto* tends to overthrow *de jure* relationship. For instance, in line with Berle and

Means (1991), he explained that corporations are ruled by those who possess and control crucial factors of production. In the “planning system,” this factor is “organized intelligence” (1967). That is why he thought that a “technostructure” rather than its owners controls modern corporations.

His contribution to Law and Economics is linked to his analysis of the structure of the American economy. In the first opus of his trilogy, *American Capitalism*, he explained that monopoly and oligopoly are now the norm rather than the exception. Thus, the Antitrust Legislation, which is embodied by the Sherman and Clayton Acts, is irrelevant. Whereas some economists pleaded for an enforcement of the antitrust laws against increasing monopoly and monopolistic power, Galbraith explained that competition among giants (corporations, unions, workers’ and buyers’ cooperatives) is susceptible to lead to some equilibrium (1952b). This is at the heart of his idea that “countervailing power” is the new regulative mechanism of the American economy. “In Galbraith’s theory the offsetting power of groups on opposite sides of the market fills the breach, and market power is thereby kept from upsetting the allocative and distributive mechanism” (Peterson 1957). In this regard, he dismissed the Clayton Act for serving as a means to dismantle the bargaining power of Unions rather than the original market power of giant modern corporations.

In *The Affluent Society*, Galbraith explains that antitrust laws were defended by economists since they aim to protect consumers from abuses and to struggle against inequalities. However, in the affluent society, “increased production” is becoming a substitute to “redistribution” (1958). Thus, antitrust laws are anachronistic in American modern capitalism. They are a “charade” according to Galbraith since he considers that big corporations are more efficient to achieve increasing outputs. He notes that “it is at least amusing that during both World Wars the enforcement of the antitrust laws, the traditional design for ensuring greater resource-use efficiency, was suspended” (1958). With the second opus of his trilogy, Galbraith belongs to “a minority of economists,” who consider that “the antitrust laws have outlived their

usefulness” and are unable “to deal with the phenomenon of oligopoly” (Breit and Elzinga 1968).

Galbraith pursues such a line of reasoning in *The New Industrial State*. American conception of antitrust laws is a paradox. On the one hand, there is a deep ideal of competition requiring the absence of market power, thanks to the enforcement of the antitrust laws. On the other, there is an ideal American way of life, which requires big corporations in order to achieve increasing outputs. “No one can ask [a firm] to be an oligopolist for the purposes of capital investment, organization and technology and to be small and competitive for the purposes of prices and allocative efficiency. There is a unity in social phenomena which must be respected” (1967). There are some other contradictions. Regarding antitrust legislation, monopoly is illegal. But oligopoly without overt collusion, even if it has the same economic consequences, is not. Moreover, antitrust laws are sometimes used to condemn two small merging competitors rather than a single firm that controls a greater extent of market shares. His judgment is without appeal: “present enforcement [of antitrust laws] attacks the symbol of market power and leaves the substance” (1967).

Instead of relying on antitrust laws, Galbraith thinks that direct social control of corporations is more efficient. This preference is first understandable because he thinks as every institutionalist that concentration is “the inevitable product of economic imperatives” (Muller 1975). Then, his experience at the head of the Office for Price Administration convinced him that direct negotiation between corporations and public administrations is workable. He argues that price control is a more effective means for avoiding oligopolies’ abuses (1952a, 1967). Muller, considering the relevance of Galbraith’s analysis, adds that direct public control and indirect ones, through antitrust laws, could be complementary so as to reduce the undesirable effects of market power.

This succinct summary of Galbraith’s conception of antitrust laws is one of his numerous innovative analyses. Nowadays such a reflexion appears even more original since Competition Policy, especially in the European Union, has

become a substitute rather than a complement to Industrial Policy.

Impact and Legacy

John Kenneth Galbraith did not give birth to a school of thought, since on the one hand he was on the fringe of academia and on the other hand he did not like to teach. James Galbraith sums up that “the Galbraith paradox is that the great theorist of organizations worked alone – he was an intellectual entrepreneur” (2007). Some of his works are largely known, others deserve to be. The impact of Galbraith’s works on postwar economics was however crucial, since he always refused to abandon his critical glance towards economics.

Games

Ulrich Blum

Faculty of Law and Economics, Martin-Luther-University of Halle Wittenberg, Halle, Germany
University of International Business and Economics, Beijing, China

Abstract

This entry begins by setting games within the general framework to demonstrate their conceptual importance for describing this activity of humankind. Then the concept of merging economics and mathematics into what is called game theory is developed. Descriptions of important properties, definitions, and typical examples of games are provided.

Definition

A game is a structured interaction of at least two players. It consists of rules that set the institutional framework of possible moves. These lead to outcomes that are subject to individual preferences, which generate the incentives to play. If individual ends are incompatible, dilemmata develop, which make the underlying strategic interaction particularly visible.

Games and Science

Even before John von Neumann and Oskar Morgenstern (1944) merged mathematical and economic theory in their groundbreaking work *Theory of Games and Economic Behavior* games were attracting interest in other fields. For instance, Johan Huizinga (1933) looked at games from a psychological perspective showing that they are a fundamental force and a formative element of culture as defined by philosophical anthropology. Games date back to a time before the development of humankind: Many creatures, especially primates, but also other mammals as

well, show game-related behavioral patterns as an expression of rivalry. From a phylogenetic perspective, animals play, and from an ontogenetic perspective, games are incorporated into the existence and the development of the personal individuality of humankind. Games represent a field of tension between conflict – mankind’s aggression – and cooperation, the attempt to bind interests. If we say “a game is captivating,” then we metaphorically combine these antagonistic aspects in one sentence. In history and social sciences, managing conflict and mapping it in parlor games have always accompanied human development. In fact, John von Neumann (1928) looked at this issue in his first book on game theory. The greatest works on strategy, which are often compared today to game-theoretic models, were developed by scholars like Sun Zi (544–466 BC) from China or Carl von Clausewitz (1780–1831) from Germany. The *Art of War* (~500 BC, 2003, 2007) and *On War (Vom Kriege, 1832)* are two classic books about leadership under conditions that involve strategic, operational, or tactical interaction – an aspect of humankind that is also found in important religious works such as the Talmud, the Bible, and the Koran.

The work of John von Neumann (1928) and Oskar Morgenstern triggered not only a broad scientific development of game theory, such as the work by John Nash (1950) on equilibria published half a decade later, it also triggered a very strict observation of reality and its dilemma situations. On the level of political thinking, the concept of zero-sum games is perhaps the best-known outflow and potentially the least understood. In terms of the military, the concept of a credible threat during the Cold War was the direct result of game-theoretic thinking.

Economic and Political Aspects of Game Theory

If human rivalry is to be oriented toward a common good, and if the social contract written by societies is to be productive, the distinction between institutional rules and the moves allowed within this framework is of utmost importance.

This relates to extending competition in markets to the idea of competition among institutions, especially public institutions. According to the philosophy of Immanuel Kant (1787) and, in particular, his concept of the “categorical imperative,” economic institutions should be designed in such a way that the maxim of their implementation can be accepted as a general rule or regulation. Thus, dilemmata reach beyond individual rivalry, extending to the interaction between institution setters, institutions, and their efficiency in relation to other institutions, thus binding together economics and law. This lies at the core of the very successful German social market economy in the tradition of Walter Eucken (1952) and Ludwig Erhard (1957). Rules are to be set so that they are self-enforcing and follow mankind’s open incentive concept. In such a world, games have two properties: rivalry over better arrangements at the higher institutional level and rivalry within the economic or social world below this roof. This addresses two aspects accentuated by game theory: hierarchy and dynamics. Who and how are the rules set for games, how open are they to long-term change, and who is in charge? Furthermore, with regard to moves (the complete set of which is called strategies), how can players learn to distinguish between “good” moves and “bad” moves? The final chapter will take up this subject using institutional competition as an example.

The rest of the entry is structured as follows: First we will look at the information side of game theory and the prerequisites for efficient activities. Then we will look at how one type of game may switch to other type when circumstances change. Finally, we will look at dynamic contexts.

The General Structure of Games

A game is a model of strategic (or tactical) interaction between players who have sets of possible actions. Since the model captures this interaction between the players, outcomes are interdependent. Dixit and Nalebuff (2010) is an introductory text that requires little formal experience. Standard textbooks are Rasmusen (2006) or Osborne and Rubinstein (1994). Binmore (1991) adds humor

Games, Fig. 1 Extensive form of a two-player game

Games, Fig. 2 Prisoner's dilemma game

		Player 2	
		silence	fink
Player 1	silence	- 1 / - 1 A C	- 9 / <u>0</u>
	fink	<u>0</u> / - 9 B D	<u>- 6</u> / <u>- 6</u>

to theory. Players come up with strategies s and have preferences that are modeled by ordinal pay-offs or cardinal functions, for instance, production functions $p(.)$ or utility functions $u(.)$. In its extensive form, the game starts with two possible moves from the first player's strategy set (s_1^1 and s_1^2). This is followed by the moves of the second player. Figure 1 illustrates the sequential structure.

One of the best-known games is the prisoner's dilemma. The fundamental idea is straightforward: A murder has been committed and the police apprehend two suspects tramping in the area. They lock them up separately and have them interrogated by an attorney. The vagrants would be best off if they both remained silent; then they would be sentenced to only 1 year each for vagrancy. However, if one of them finks (cheats, defects) and accuses the other, he will be set free and the other will be jailed for 9 years. If both accuse the other person, they will both be jailed for 6 years. To all extent and purposes, it

would be socially efficient to remain silent. However, under the absence of coordination, the best possible strategy is to accuse the other, which, however, produces an inferior outcome (Fig. 2).

If both defendants remain silent, the outcome is better than if they accuse each other (both payoffs are strictly higher values). The best strategies for one player against the other are underlined. However, this advantage does not exist with respect to the other two pairs of payoffs. In addition, the payoff resulting from mutual accusation remains unchanged in the sense that neither prisoner can deviate without disadvantaging himself. This leads to the following definition:

A set of player strategies is a Nash equilibrium if no deviation of any individual player's strategies (i.e. given the strategies of the other players) results in a better outcome for that player.

Results in field D are thus underlined twice as they are the Nash equilibrium.

Games, Fig. 3 Tragedy of the commons game

		all other players				
		cooperate	defect	act at 10% in consort	act at 30% in consort	act at 60% in consort
player A	cooperate	10/10	2/12	2.8/11.8	4.4/11.4	6.8/10.8
	defect	12/2	3/3	11.1/2.1	9.3/2.3	6.6/2.6

One of the most interesting games in the genre of prisoner’s dilemmas is the tragedy of the commons (Hardin 1968). In this game, a joint resource is distributed. An overexploitation and destruction of the resource can only be prevented if all parties agree to the terms of exploitation. However, under the absence of coordination, each individual will seek to achieve his/her own optimal outcome, and the resource will break down. The resource-efficient outcome will only be achieved if there is a high enough expectancy to cooperate. Figure 3 shows that this is the case if 60% act in consort. If player A then decides to defect, he will be worse off (6.6 instead of 6.8 points). This is not yet the case when only 30% act in consort.

There are many interesting dilemma situations: The chicken game models a situation where two cars approach each other on a narrow road with the question being, which car gives way to which? The battle of the sexes models a situation where a couple wants to spend their weekend away from home; he wants to go to a soccer game, while she wants to go to the theater. Both strategies on their own are incompatible with one another, and there is no joint utility-maximizing outcome. The problem in this game is that mixed strategies are not possible. A compromise can only be found, and socially efficient results can only emerge, if a mix between the two is possible, for instance, if two weekends are taken into consideration.

From these discussions, two other notions can easily be derived:

- In zero-sum games, the extent of the loss on the one side is identical to the gain on the other side.
- Zero-sum games are a special variant of constant sum games.
- In policy discussions, people think situations are zero-sum situations even when they truly are not. For instance, following Ricardo’s classic theory of comparative costs, trade is a redistribution that makes both parties better off.

Games with Functions as Payoffs

Often, games are set within a dynamic context as they develop in an evolutionary way or are played repetitively. Players are then able to gain experience, which may encourage them not to fall into inefficient Nash equilibria, e.g., into the prisoner’s dilemma trap. Another aspect is the changing of payoffs in dynamic utility or production functions, as in the following case which combines the economics of competition with the legal side of good regulations and governance. The example follows (Blum et al. 2005, section 7.2.2). In a competitive environment, the antitrust organization sets penalties, p , if competition rules are broken. The standard reward from competition is

Games, Fig. 4
Competition game

		Player 2	
		obeys rules	cheats on rules
Player 1	obeys rules	ordo-economy	one-sided power
		$s + f - g(e)$	$s - p$
	cheats on rules	$s + f - g(e)$	$s - p - g(e)$
		$s - p - g(e)$	$-p$
		One-sided power	destruction of market

Games, Table 1 Basic game structures

Basic game	Line player (player 1)
Prisoner's dilemma	$B_1 > A_1 > D_1 > C_1$
Chicken game	$B_1 > A_1 > C_1 > D_1$
Assurance game	$A_1 > D_1 > C_1$ and $A_1 > B_1$
Social optimum	$A_1 > C_1 > D_1$ and $A_1 > B_1$

$s \geq 0$; it becomes zero if all players violate competition laws. An extra externality or fringe profit, $f \geq 0$, emerges if all players comply with the rules. The effort of players is given as $e \geq 0$ and the related disutility is $g(e) \geq 0$ (Fig. 4).

Table 1 lists three types of games and the structure of their payoffs, to which we have added a social-optimum outcome.

If we evaluate the outcomes, we obtain:

- **Prisoner's dilemma:** (player 1, $B_1 > A_1 > D_1 > C_1$; player 2, $C_2 > A_2 > D_2 > B_2$)

$$B_1 > A_1 (\text{or } C_2 > A_2 \text{ resp.}) \Leftrightarrow s - p > s + f - g(e) \Leftrightarrow f < g(e) - p. \quad (\text{P1})$$

$$A_1 > D_1 (\text{or } A_2 > D_2 \text{ resp.}) \Leftrightarrow s + f - g(e) > -p \Leftrightarrow f > g(e) - (p + s). \quad (\text{P2})$$

$$D_1 > C_1 (\text{or } D_2 > B_2 \text{ resp.}) \Leftrightarrow -p > s - g(e) - p \Leftrightarrow g(e) > s. \quad (\text{P3})$$

- **Chicken game:** (player 1, $B_1 > A_1 > C_1 > D_1$; player 2, $C_2 > A_2 > B_2 > D_2$)

$$B_1 > A_1 (\text{or } C_2 > A_2 \text{ resp.}) \Leftrightarrow s - p > s + f - g(e) \Leftrightarrow f < g(e) - p. \quad (\text{C1})$$

$$A_1 > C_1 (\text{or } A_2 > B_2 \text{ resp.}) \Leftrightarrow s + f - g(e) > s - g(e) - p \Leftrightarrow f > -p. \quad (\text{C2})$$

$$C_1 > D_1 (\text{or } B_2 > D_2 \text{ resp.}) \Leftrightarrow s - g(e) - p > -p \Leftrightarrow g(e) < s. \quad (\text{C3})$$

- **Assurance game:** (player 1, $A_1 > D_1 > C_1$ and $A_1 > B_1$; player 2, $A_2 > D_2 > B_2$ and $A_2 > C_2$)

$$A_1 > D_1 (\text{or } A_2 > D_2 \text{ resp.}) \Leftrightarrow s + f - g(e) > -p \Leftrightarrow f > g(e) - (p + s). \quad (\text{A1})$$

$$D_1 > C_1 (\text{or } D_2 > B_2 \text{ resp.}) \Leftrightarrow -p > s - g(e) - p \Leftrightarrow g(e) > s. \quad (\text{A2})$$

$$A_1 > B_1 (\text{or } A_2 > C_2 \text{ resp.}) \Leftrightarrow s + f - g(e) > s - p \Leftrightarrow f > g(e) - p. \quad (\text{A3})$$

Games, Fig. 5 Efficient areas of the competition game. (Source: Blum et al. 2005, p. 191)

If we plot these results on a graph, we obtain the following result, which is illustrated in Fig. 5. It seems that good competition regimes depend on credible penalties; sufficient externalities for good competitive behavior that can be internalized, i.e., through long-term growth; and a limited disutility of effort, i.e., limited levels of transaction costs for compliance.

true abstraction of reality – otherwise, failure can be bitter. In summer 2015, Greek finance minister Varoufakis made this experience when trying in vain to provoke the lender Troika in a poker-type manner and through impulsive behavior in order to improve his negotiation position, a strategy already proposed 50 years ago in the Strategy of Conflict by (Schelling 1960).

Cross-References

What Can Be Learned from Game Theory

Game theory is a formal tool that shows the extent to which the outcomes of different decisions interact, especially if players have opposing goals. It provides a rigorous analytical environment for evaluating efficiency in static or dynamic environments. Although the ability to model reality in a very concrete way is limited, the overall structural messages are extremely important in understanding how to manage dilemma situations. In addition, players should check whether the game is a

GE/Honeywell

Philipp Schumacher
Wildau Institute of Technology, Technical
University of Applied Science, Wildau,
Brandenburg, Germany

Definition

The GE/Honeywell case, one of the most controversial merger cases in the history of European

merger control, was subject to a long and heated transatlantic debate on the vertical and conglomerate aspects of the European Commission's 2001 prohibition decision. However, horizontal overlaps in the specific markets for aircraft and marine engines were, ultimately, the only reason given by the Court of First Instance for upholding the controversial decision.

The GE/Honeywell Case

In 2001, the attempted US\$ 45 billion merger between General Electric Company (GE) and Honeywell International, Inc. could have become the largest deal of its kind in industrial history. However, while the U.S. Department of Justice Antitrust Division (DoJ) allowed the merger on the condition that minor structural remedies be carried out, the European Commission prohibited the merger (European Commission 2001a, b). Although the Court of First Instance (CFI) criticized the Commission's analysis of the vertical and conglomerate effects of the merger, it dismissed GE's appeal in 2005, upholding the prohibition decision based on alleged horizontal effects.

GE is a diversified conglomerate and participates in a large variety of markets worldwide. The main industries it served in 2001 were: aircraft engines, transportation systems, industrial systems, power systems, plastics, lighting, medical systems, domestic appliances, broadcasting (via NBC), financial services, and information services. GE's only independent competitors in the supply of civil aircraft engines were Pratt & Whitney, part of United Technologies (USA), and Rolls-Royce (UK). GE also owned one of the world's largest lease aircraft fleets through GE Capital Aviation Services (GECAS).

At time of merger proposal, Honeywell International was a diversified technology and manufacturing company, serving customers worldwide with aerospace products and services; control technologies for buildings, homes, and industry; automotive products turbochargers; and speciality materials. Its aerospace division had a strong position in flight control systems, the

combination of cockpit displays, computers, and software that control the aircraft.

There are a large number of publications available on the GE/Honeywell case which may be categorized by five groups. Firstly, there are official publications from the European Commission, the CFI, and the US DoJ. A second group of literature mainly investigates the divergent outcomes and discusses which merger control system is superior, comprising Varian (2001), Jin (2002), Kolasky (2002a, b, c, d), Burnside (2002), Hochstadt (2003), Emch (2004), Evans and Salinger (2002), Pflanz and Caffara (2002), Ruffner (2003), Morgan and McGuire (2004), Schnell (2004), Fox (2002a, b), Girardet (2006). Thirdly, there is a large body of economic and legal literature focusing on parts of the EC decision. Here, the focus is particularly on *conglomerate effects*, i.e., bundling and leveraging, which received most of the scientific community's attention, (e.g., Briggs and Rosenblatt 2001, 2002; Drauz 2002; Emch 2003; Reynolds and Ordovery 2002; Choi 2001; Nalebuff 2002; Grant and Neven 2005; Patterson and Shapiro 2001). The fourth group of literature analyses the ruling of the Court of First Instance comprising Howarth (2006), Montag (2006), Pflanz (2006), Kolasky (2006), Weidenbach and Leupold (2006), Schwaderer (2006, 2007), Fox (2006), von Bonin (2006). Representing the fifth group, Schumacher (2010, 2013) shows that in contrast to the decision of the European Commission and the CFI, the merger would not have led to anti-competitive *horizontal effects*. According to the two-level approach of the European Commission, firstly the competitive situation of the engine manufacturer in relation to its direct customer, the aircraft or marine vessel manufacturer, and secondly the competitive effects in the respective market of end-use applications must be considered. Schumacher (2010) shows that GE was not in the position to exert market power prior to the merger and would not have been *ex post*. Applying the new EC Merger Regulation of 2004 and its Horizontal and Non-horizontal Merger Guidelines or its 2001 predecessor, an overall competitive appraisal has to go beyond the definition of the relevant market and the calculation of structural indicators such as market shares.

Assessment of the competitive closeness, firstly, of the parties' aircraft engines and, secondly, of aircraft powered by these engines requires the analysis of bidding data and technical characteristics. The engine markets affected are world-wide bidding markets characterized by volatile market shares, the high importance of after-sales revenue and profitable outside options. Based on publicly available data, information from aerospace professionals and industry knowledge, the conclusion of an effects-based analysis of GE/Honeywell is diametrically opposed to the Commission's decision regarding both horizontal and nonhorizontal aspects. As shown in similar complex aerospace mergers GE/Smiths Aerospace (2007) and UTC/Goodrich (2012), the "more economic approach" to European merger control, including empirical analysis firmly grounded in industry-specific expertise, can help to avoid a pro-competitive merger being prohibited again based on speculative theories of harm inconsistent with the realities of the case.

Gender Diversity

Isabel-María García-Sánchez

Universidad de Salamanca, Salamanca, Spain

From a business perspective, gender diversity represents the heterogeneity of a workforce in terms of gender, including that of top management and the board of directors. Gender occupational segregation is a phenomenon which is present in most countries, regardless of economic conditions and the existence of anti-discrimination laws that ensure full citizenship for women. However, the presence of women in positions of power and decision-making in organizations and in public and private institutions is virtually nonexistent. Most analysts agree that organizational dynamics are the main obstacle to the career advancement of women and that these are still dominated by androcentric values that exclude them from decision-making. This still does not solve the problem of reconciling work with privacy.

The inclusion criterion for gender diversity in organizations corresponds to a strategy of promoting the participation of women in positions of responsibility. The central idea of the concept of diversity is the maximum utilization of the potential of heterogeneous groups, i.e., how they are different in terms of gender. Variability is emphasized, so that each person is valued for what they are and what they can contribute with regard to their personal characteristics. A diversity strategy gives organizations the ability to attract and retain diverse talents which are representative of both sexes. In this sense, gender diversity recognizes that there is no single way to work but that labor plurality may be advantageous for an organization, as it encourages innovation and complementary perspectives.

Generalized differences were identified in the gender management practices due to women and men having several approaches to overall style, decision-making, and interpersonal relationships. Several authors, such as Robinson and Dechant (1997), suggest that the incorporation of women into the main management bodies entails

a significant increase in business due to the economic result set of skills, knowledge, and personal experiences of women. Women have a higher ability to achieve a better understanding of the demands of customers, increasing their chances of entering new markets (Carter et al. 2003), in order to promote an effective resolution of problems and evaluate alternatives (Rose 2007) and to hire the best executives and directors to limit bias against minorities (Campbell and Minguez-Vera 2008). All of this will result in positive signals being sent out to the labor market and the generation of capital for products that will reduce the costs borne by companies (Rose 2007).

Additionally, the proponents of gender diversity on the board feel that their presence is meant to increase business organizational values and business results through the creation of new knowledge and perspectives (Carter et al. 2003). These are the key factors in the process of adopting sustainable forms of behavior in the economic sphere. Furthermore, according to Calas and Smircich (2004), with regard to the traditional feminine qualities, rhetoric is a rationale that must include the value being held for radical changes and for configuring a new business model that creates value not only for shareholders but also for different stakeholders.

The above characteristics are specified in the globally proven fact that women are more sensitive to other perspectives of corporate behavior, have a greater ability to identify the needs of different stakeholders, and can provide more opportunities to satisfy them (Brennan and McCafferty 1997). Thus, counselors need to be more participative and democratic and show more group spirit than their colleagues in promoting participation and dialogue within the board and, by extension, in encouraging greater communication and paying more attention to the interests of the various stakeholders (Eagly et al. 2003). They also need to have had a greater number of experiences outside the business world (Hillman et al. 2002). All of the above creates, ultimately, an increased focus on CSR (Singh and Vinnicombe 2004).

However, from the point of view of value creation, the presence of more women may also involve a number of disadvantages associated

mainly with the diversity of opinions and the appearance of discrepancies that may cause delays in decision-making (Smith et al. 2006).

Genocide

Charles H. Anderton¹ and Jurgen Brauer²

¹College of the Holy Cross, Worcester, MA, USA

²Hull College of Business, Georgia Regents University, Augusta, GA, USA

Abstract

The entry defines crimes of mass atrocity, such as genocide, provides data on their intensity, and discusses domestic and international

institutions formed to address the crimes. In addition, the entry briefly surveys the economic literature on mass atrocity crimes from theoretical and empirical perspectives. It pays particular attention to the economics of international law.

Definition

By combining the Greek *genos* (a people, tribe, race) and the Latin *cide* (to kill), Raphael Lemkin (1944, p. 79) invented the word genocide. Article 2 of the 1948 United Nations (UN) Convention on the Prevention and Punishment of the Crime of Genocide defines *genocide* as “any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group, as such: (a) Killing members of the group; (b) Causing serious bodily or mental harm to members of the group; (c) Deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; (d) Imposing measures intended to prevent births within the group; (e) Forcibly transferring children of the group to another group” (United Nations 1948). As of 31 October 2014, only 146 UN members are Party to the Convention.

Data, Mass Atrocity Crimes, and Institutions

Data

In a summary of large-sample datasets on atrocities involving civilians, Anderton (in Anderton and Brauer forthcoming; henceforth “in A/B forthcoming”) identifies 201 distinct cases of state-sponsored genocides and mass atrocities (GMAs) from 1900 to 2013, 43 state-perpetrated genocides from 1955 to 2013, and 34 GMAs perpetrated by non-state groups from 1989 to 2013. Some well-known genocides include the Armenian genocide (1915–1918; estimated fatalities ~1.5 million), the Holocaust (1933–1945; ~10 million), Cambodia (1975–1979; ~1.9 million), Rwanda (1994; ~0.8 million), and Sudan-Darfur (2003–2011; ~0.4 million). A cautious estimate of

intentional civilian fatalities associated with the 202 state-perpetrated GMAs since 1900 is 84 million. Less well-known are non-state perpetrated atrocities such as conducted by the so-called Islamic State, with estimated fatalities of 8,198 from 2005 to 2013 (see Uppsala Conflict Data Program at <http://www.pcr.uu.se>).

Mass Atrocity Crimes

As defined in the UN Convention, *genocide* is the intentional destruction, in whole or in part, of a specific group of people. In non-genocidal *mass killing*, perpetrators do not seek to destroy a group as such (Waller 2007, p. 14). *Crimes against humanity* encompass widespread or systematic attacks against civilians involving inhumane means such as extermination, forcible population transfer, torture, rape, and disappearances. *War crimes* are grave breaches of the Geneva Conventions including willful killing, torture, willfully causing great suffering or serious injury, and extensive destruction and appropriation of property. *Ethnic cleansing* is the removal of people of a particular group from a state or region using means such as forced migration or mass killing (Pergorier 2013). *Violence against civilians* (VAC) can incorporate mass atrocities but it also includes incidents that are relatively small, specifically, less than 1,000 per case or per year. Along with genocide, crimes against humanity, war crimes, and ethnic cleansing are both legal and scholarly terms.

At the Nuremberg trials of 1945–1946, the International Military Tribunal found none of the accused guilty of crimes committed prior to the outbreak of war on 1 September 1939; litigation was limited to atrocities during wartime (Schabas 2010, pp. 126–127). Lemkin's (1944) and the UN's conceptions of genocide were novel precisely because they spoke to criminal acts committed in wartime or in peacetime. Nevertheless, the UN definition of genocide has been subject to critical scrutiny by scholars, for instance in regard to groups left out (e.g., political), how to identify "intent," the inability of the Convention to prevent genocide, the relationship of genocide to other atrocities, and misuse of the term (e.g., Curthoys and Docker 2008). The UN definition of genocide

has not expanded since 1948 to include other groups, but international criminal law has evolved. Schabas (2010, p. 141) maintains that the expanded concept of crimes against humanity has "emerged as the best legal tool to address atrocities" and "genocide as a legal concept remains essentially reserved for the clearest cases of physical destruction of national, ethnic, racial, or religious groups."

International and Domestic Institutions

The twentieth and twenty-first centuries display the emergence and growth of international and domestic laws designed to prevent, punish, and/or foster restitution for atrocity crimes. Table 1 shows a selection of such institutions as well as sources that provide further information. Adjudication of mass atrocity crimes began in earnest following World War I with the establishment of the Turkish Military Tribunal (TMT) (1919–1920), which prosecuted organizers of the Armenian genocide. The trials, characterized as "a milestone in Turkish legal history" (Dadrian 1997, p. 30), revealed the systematic planning behind the genocide, enrichment of perpetrators through looting of victims' assets, and the lack of military necessity for the forced relocation of Armenians. However, the TMT convicted only 15 men among the hundreds who orchestrated the genocide (Dadrian 1997).

Following World War II, the International Military Tribunal (IMT) at Nuremberg was established in which leading officials were tried for war crimes and crimes against humanity (1945–1946). Twelve Nazi leaders received the death sentence and many others were given long jail terms. The trials had an important influence on the growth of international criminal law including the 1948 Genocide Convention, the International Criminal Tribunal for the Former Yugoslavia (ICTY) established in 1993, the International Criminal Tribunal for Rwanda (ICTR) established in 1994, and the International Criminal Court (ICC) ratified in 2002. As of December 2014, the ICTY had indicted 161 people for atrocity crimes associated with the wars in the former Yugoslavia in the 1990s. As of December 2014, the ICTR had indicted 95 people for atrocity

crimes associated with the 1994 civil war and genocide and it established the legal precedent that mass rape during wartime is genocidal. Following the huge backlog of cases awaiting trial in Rwanda, the government turned to the Gacaca court system, based on traditional law developed within communities (Bornkamm 2012). As of October 2014, the ICC has indicted 36 individuals for atrocity crimes including three current or former heads of state: Omar al-Bashir (Sudan), Uhuru Kenyatta (Kenya), and Laurent Gbagbo (Côte d'Ivoire). According to its Statutes, the ICC has jurisdiction with respect to genocide, crimes against humanity, and war crimes.

Another important international genocide development occurred at the 2005 UN World Summit, in which member states unanimously adopted a norm known as the *Responsibility to Protect* (R2P). R2P was part of the impetus for UN Security Council Resolution 1973, passed on 17 March 2011, which authorized member states to take actions, including enforcement of a no-fly zone, to protect civilians from attacks by the

Libyan military. Nevertheless, the UN's R2P resolution has no legal force (UN Doc. A/RES/60/1, paras 138, 139).

Following the Nuremberg trials and the UN Convention, several dozen nations have developed domestic laws to put on trial suspected Nazi war criminals and/or perpetrators of more recent atrocities (Schabas 2003). For example, in 2000 the Chilean Court of Appeals lifted former President Augusto Pinochet's immunity from prosecution, paving the way for trial for his role in civilian atrocities that occurred during his leadership (Pinochet died prior to any conviction). The case is notable not only because it involved a state's prosecution of its former leader, but also because Pinochet's initial arrest occurred in London based on an application of "universal jurisdiction" by European judges. Universal jurisdiction is a principle by which a state (or states, in the Pinochet case) asserts its right to prosecute a person for an alleged crime regardless of the crime's location and the accused's residence or nationality (Lunga 1992).

Not shown in Table 1 are formalized norms within for-profit and non-profit organizations designed to inhibit complicity in atrocities. The ICC followed the ICTY and ICTR in having jurisdiction only over “natural persons” and not “legal persons” (Cernic 2010, p. 141), which ruled out prosecution of corporations complicit in genocide (individual agents within corporations can be tried). Multinational corporations have been complicit in genocide in many cases, but have not usually faced prosecution (Kelly 2012). Nevertheless, there have been legal efforts, including use of the US Alien Tort Claims Act, to bring litigation against corporations for alleged complicity in atrocities and other human rights abuses. Such litigation is leading companies to develop norms to avoid such complicity (Michalowski 2013).

Theoretical and Empirical Aspects

This section asks: What are (some of) the risk factors that economic theory and associated empirical work point to, i.e., what makes the risk nonzero ($r > 0$)? The section thereafter asks: How can genocide risk be reduced below 1 ($r < 1$)?

Theoretical Perspectives

Formal economic models of genocide are relatively new in the literature on conflict, peace, and security between and within states. Verwimp (2003), Ferrero (2013), Anderton and Carter (2015), and Anderton and Brauer (in A/B forthcoming) present nonstrategic constrained optimization models to highlight conditions under which a political authority would choose genocide as part of its goal of controlling territory or government (or both). The models reveal conditions in which genocide has a low opportunity cost for the authority, specifically, when genocide enhances the authority’s control in the context of crisis or war, is not too disruptive to economic activities (e.g., trade), is conducive to looting victims’ wealth, and is not likely to generate third-party intervention. Under such conditions, genocide is “cheap,” and a positive amount demanded can exist. Genocide prevention requires that the opportunity cost of genocide is made high through sanctions, credible threats of third-party

intervention to help victims and/or oppose authorities, threats of prosecution, and surveillance of atrocities which can lead to “naming and shaming” of perpetrators. In addition to modeling genocide risk factors, Anderton and Brauer (in A/B forthcoming) use a Lancaster household production model to study the “optimal” choice of genocidal techniques (e.g., mass killing, starvation, forced relocation, etc.) by a regime that has already chosen genocide. Among the results is a “bleakness theorem” in which protection policies along one or just a few dimensions have relatively little overall effect, and sometimes no effect, in protecting victims.

Game theory models of genocide consider strategic interactions between warring groups and/or between an oppressive in-group and an out-group in which intentional destruction of civilian groups is part of war tactics or strategy. For example, Azam and Hoeffler (2002) identify conditions in which warring sides use violence against civilians to strengthen themselves in their strategic interaction. Focusing on the years preceding the 1994 Rwandan genocide, Verwimp (2004) develops a four-player game to model the strategic interactions among the regime, the domestic opposition, a violent rebel group, and the international community. Within the game, eliminating the moderate Hutu opposition and exterminating the Tutsi can be “optimal” strategies. Anderton (2010) draws upon the bargaining theory of war to show how severe threat against an authority group or an incentive to eliminate a persistent rival can lead to genocide as an “optimal” choice. Anderton (2010) and Gangopadhyay (in A/B forthcoming) use evolutionary game theory to model how genocide can become socially contagious (acceptable) among “ordinary people.” Vargas’ (in A/B forthcoming) model of contestation between a government and a rebel group reveals the incentives of each to side to kill the civilians who are supporting the enemy. Within the model, Vargas finds that the strengthening of either side can have ambiguous effects on the total number of civilians killed, thus showing that third-party support for one side or the other can potentially increase civilian killing. Esteban et al.’s (forthcoming; in A/B forthcoming) inter-temporal models of

contestation between a government and a rebel group reveal several important and sometimes counterintuitive results. In particular they find that new discoveries of resources, democratization of the polity, and third-party intervention to defend vulnerable civilians can enhance incentives for mass killing if they materialize under the “wrong” conditions.

The lessons of constrained rational choice and game theory models for thinking about the emergence of laws designed to punish and prevent genocide are critical. Laws that come into being will be evaluated by potential perpetrators of genocide as part of the constraint set being faced. Such agents, if determined to carry out genocide, have an extensive menu of inputs for working around such laws to achieve objectives. Laws to punish or prevent genocide must consider the multiple options available to potential perpetrators and the potential for laws to lead to unintended consequences. This concern is especially significant in the context of strategic interplay between a government, rebel organization, and possible third-party intervener. If not carefully designed, law to prevent and punish genocide can serve to increase incentives for atrocities. (On the design of law, see the next section.)

Perspectives from behavioral economics also help to study genocide (e.g., Anderton and Brauer; Slovic, Västfjäll, and Gregory, both in A/B forthcoming). Especially important is the reference-dependent objective function of one or a few leaders who have become accustomed to control of political, economic, and/or territorial goods. Experiments in behavioral economics often find evidence of *loss aversion*, in which, relative to a reference point such as current hold on power, subjects believe they are worse off from a loss than a similar gain leads them to feel better off. The notion of loss of power as a form of extreme crisis or existential threat in the minds of leaders is palpable in many genocide case studies (Totten and Parsons 2013). Such losses, coupled with the behavioral phenomenon of loss aversion, suggest that leaders could make extreme choices including repressive violence or genocide to avoid loss (Midlarsky 2005, pp. 64–74).

Empirical Perspectives

About 30 published large-sample cross-country empirical studies of genocide or other forms of VAC risk or seriousness exist (see Anderton 2014; Anderton and Carter 2015; and Hoeffler in A/B forthcoming). Most of these focus on genocide risk or severity from the perspective of *countries*, and thus they focus on the problem of genocide from the “macro” or top-down perspective. Another branch of empirical genocide literature focuses on particular countries, regions, or locales in which genocide took hold and spread, thus emphasizing a “micro” or bottom-up perspective. While almost all of the empirical studies of genocide in the literature focus on risk or seriousness based on historical data, studies are emerging with an emphasis on forecasting (e.g., Rost 2013; Butcher and Goldsmith in A/B forthcoming).

The most prominent macro-empirical study of genocide risk in the literature is by Harff (2003), who focused on a sample of states that experienced “state failure” (e.g., civil war, regime collapse) from 1955 to 1997. Of 126 state failures in the sample, 35 led to genocide. Conditioned on state failure, Harff used logit analysis to identify six significant risk factors for genocide onset: magnitude of political upheaval; history of prior genocide; exclusionary ideology held by the ruling elite; autocratic regime; ethnic minority elite; and low trade openness. Failing to make the list of significant risk factors was economic development, which Harff proxied by infant mortality. Another important macro-empirical study of mass atrocity risk is Easterly et al. (2006), who assemble a dataset for many countries for the period 1820–1998. Among their key results, they find that mass atrocity is significantly less likely at high levels of democracy and economic development, in which the latter was proxied by real income per capita.

Regarding potential *economic* risk factors for genocide, subsequent empirical research suggests that Harff’s result for trade is not robust with most studies reporting no significant impact of trade on atrocity risk. In addition, Harff’s result on economic development is open to question because an inverse relationship between real income per capita and atrocity risk or seriousness is one of the few modest empirical regularities in the literature.

Other economic risk factors considered in the empirical literature are income inequality and resource dependence, in which no empirical regularities have yet emerged, and *economic* discrimination, which is only beginning to be considered but in which two studies report a significant positive effect on genocide risk (Rost 2013; Anderton and Carter 2015). In the emerging empirical forecasting literature on genocide, no clear results as yet stand out in regard to the roles of economic variables. In their survey of such literature, Butcher and Goldsmith (in A/B forthcoming) suggest that “while economic factors might have an underlying causal effect on the likelihood of genocidal violence in a society, as predictors in forecasting models they might be overshadowed by political or demographic factors that are more proximate to genocide onset.”

In addition to large-sample, macro-empirical studies of genocide risk or severity are country-specific, micro-empirical studies that focus on particular characteristics of a nation, region, or individuals that led to the onset or spread of atrocity (e.g., Ibañez and Moya in A/B forthcoming; Justino in A/B forthcoming). Country-specific studies typically identify historical, social, and economic conditions particular to the country and tactical and strategic aspects of war that are critical for understanding atrocity. Such finer-grained elements can be glossed over in large-sample cross-section studies. For example, Ibañez and Moya’s (in A/B forthcoming) study of Colombia reveals many dynamic, nuanced, and interrelated aspects of community and household incentives for civilians to flee violence, why some do not flee, and why contesting military forces (government, militias, rebels) tactically and strategically kill and/or force the relocation of civilians. Such complexities are obviously critical in considering laws to reduce risks of future civilian atrocities, but also in prosecuting perpetrators and designing reparations in post-genocide settings.

Economics of International Law

Despite some cases of GMA having been brought to trial in national and international courts or

tribunals – the Armenian trials in Turkey, the Nuremburg trials, the Pinochet case, and more recent tribunals regarding Cambodia, Rwanda, and the Balkan wars of the 1990s – the overall record of reducing the risk of GMA to below certainty ($r < 1$) is only mildly encouraging. There are several reasons for this. First, even assuming away issues of ignorance and apathy, as a matter of *economics*, unilateral action runs into the problem of sufficient scale and multilateral, collective action into issues related to strategic behavior, free-riding, coordination, agency, benefit appropriation, and cost shifting. Even assuming that none of these pose a problem, all options rely on the existence of well-codified and well-functioning regimes of national and international law and their enforcement. Second, as a matter of *law*, then, reducing GMA risk is difficult because (a) state sovereigns are cautious to accede to any international treaty that may later expose them to legal liability in the first place and (b) because state sovereigns generally do not cede jurisdiction over nonstate GMA actors to international bodies (e.g., Nigeria maintains jurisdictional prerogative over Boko Haram; and if a nonstate actor prevails in an internal conflict it may not be brought to justice at all). And third, as a matter of *institutional design*, these topics bring up questions, to echo Oliver Williamson (1999), as to what kind of bad GMAs are in the first place and, correspondingly, what kind of good GMA-related laws are, and how to best supply them.

On the demand (or usage) side, are GMA and GMA-related law private (excludable and rivalrous), public (nonexcludable, nonrivalrous), club (excludable, nonrivalrous), or common-resource pool (nonexcludable, rivalrous) bads or goods, or some changing mixture thereof? And on the supply side, are they best provided by private or public actors, or some changing combination of the two, and what is the technology of their production (e.g., best-shot, weakest-link, aggregate effort, or variants thereof)? What sort of issues in agency, transaction costs, and institutional design arise? While a considerable global public goods (GPG) literature has sprung up in economics (e.g., Kaul and Conceição 2006 and literature cited

therein), application to the design of international law as an instance of GPGs is thin in general and almost entirely absent in regard to law and GMA (see, e.g., a recent symposium of papers in the *European Journal of International Law*, 23(3), 2012).

As regards GMAs, we suggest that indiscriminate chemical weapons gassing may be conceptualized as a *public bad* for the affected population if it is neither feasible to exclude oneself from the gassing nor feasible to seek effective shelter (there can be no rivalry for shelter if there is none to be had). Those who do manage to crowd into a shelter, however, partake in the benefit it offers, the shelter being a common-resource pool good, while those left behind on the street suffer a *common-resource pool bad* (nonexclusionary but rivalrous). In contrast, genocide would be a *club bad* precisely because its architects differentiate and select victims. Finally, examples of a *private bad* suffered in violent conflict include un-orchestrated rape in war or the death of a soldier in the performance of his or her duties (the “expected” bad in war, but not a war crime). Similarly, in regard to the good that GMA-related law may provide, international law of war is intended as a GPG in that all soldiers share in the benefits the law provides and none of them are excluded. In contrast, national law is private to the state whose legislative body passes it: It excludes nationals of other states and reserves benefits to its own nationals. But all international law is effectively a club good, benefitting those who accede, and becomes a pure GPG if and only if *all* states become Party to the treaty in question. In practice, however, it is conceivable that benefits can be withheld so that the benefits law offers become rival to those with the means to access its provisions when needed. Thus, while the Genocide Convention is (not quite) a global public good in principle, the evident practice of “too little, too late” suggests that its enforcement is rivalrous and therefore constitutes a common-resource pool good.

Even this cursory “walk around goods space” (Brauer and van Tuyl 2008, Chap. 8) suggests that the good (or bad) in question can take various forms and that each may change across

geographic space and time. Neither the goods nor the bads are necessarily unitary (of a single form), and to conceive of GMA simply as a global public bad requiring a global public good response may be inadequate. Moreover, as Shaffer (2012) points out, international laws can be rivalrous to each other and their construction is designed, in part, to trade off against multiple national laws (legal pluralism).

In addition, economically efficient (no under- or overprovision) GMA-law in response to GMAs may depend on the summation technology of GMA production. Applying Hirshleifer’s (1983) insight, that some GPGs are best provided as best-shot products (the single-best effort suffices; no need for anyone else to contribute to its provision), weakest-link products (the weakest provider limits the good’s effectiveness), or aggregate effort products (the more is provided by all, the better for all), Shaffer (2012; esp. Table 2, p. 690), argues that best-shot GPGs are best dealt with in global administrative law, weakest-link GPGs by fostering legal pluralism, and that only aggregate effort GPGs may require a global constitutionalist approach. To illustrate, when a single country has effectively become the world’s only superpower to intervene in other states’ (GMA or GMA-alleged) affairs, it may be tempted to overreach or under-reach according to its own cost-benefit calculated perception of its Responsibility to Protect, regardless of the wishes of all other UN members. But superpower intervention or nonintervention solely at its own discretion challenges global legitimacy (the US is often accused in this regard; France, in regional interventions, less so). Such situations, Shaffer (2012) argues, are best dealt with by global administrative law which might hold the “incumbent” of the superpower “office” responsible for its actions. We imagine (since Shaffer does not address GMA), that instead of a Genocide Convention, there might exist an UN-approved automatic trigger obligating the superpower to intervene in cases of GMA, subject to global administrative law. As of this writing, little has been theoretized in this regard.

An additional issue pertains to trans-generational global public goods. Again, this is

insufficiently theorized but probably of great importance in cases of GMAs since each event carries significant generational implications (for a review see, e.g., Ibañez and Moya in A/B forthcoming). For public goods provision, Sandler (1999) speaks for four levels of awareness rules: First, the myopic view considers making a marginal cost (MC) contribution to the provision of a GPG only up to the sum of the marginal benefits (MB) a state estimates for its own current generation, $MC = \Sigma MB$. Second, although still selfish, a forward-looking view is to include one's own offspring generations, i , such that $MC = \Sigma MB_i$. Since the expected benefits are larger, this translates into greater willingness to make a larger MC contribution. Third, a more generous view of the benefits summation includes other states' populations, j , but only for the current generation ($MC = \Sigma MB_j$). The most enlightened view of all – we call this the “Buddha rule” – sums the expected benefits across all generations across all populations, $MC = \Sigma MB_{ij}$. Since such benefit is likely to be large, it justifies correspondingly large outlays.

Finally, design criteria for GPG that would take account of goods (or bads)-space, summation technologies, transboundary, and trans-generational aspects have been discussed in the literature (Sandler 1997) but rarely in regard to GMA-related national and international law (Myerson, in A/B forthcoming, is an exception). It would appear that a fruitful field of inquiry is ready for exploration in this regard.

Geodesy

Otmar Schuster

Haus der Geoinformation, Mülheim an der Ruhr,
Germany

Abstract

Geodesy, starting as a scientific discipline exploring the size of the earth in the eighteenth century, soon produced the basis of modern land tax systems and enabled the institution of individual property rights in real estate, a backbone of the constitutional order. Geodesy stimulated the development of the modern state by data collection and land management methods. The satellite techniques and the advancement and the expansion of the sensor technology based upon the theoretical mastery of the space in methods and incoming data made the geodesy and its professionals effective in the public management and the economy. Geodesy as an economic sector

producing and managing geo-information is deeply woven in different disciplines of science, public administration, and economy but recognizable by its methods and results.

Definition

Geodesy is a discipline in science, government, land management, and industry. It addresses the shape and the shape near earth, the national government of land, the land management, and real estate property.

Geodesy: Reference Frame for the Earth

Geodesy explains the knowledge about the shape and shape near earth. It comprises specific methods which are useful to analyze tectonic movements but also to manage countries, land, and plots.

It needed more than two millennia to go back to the anthropocentric worldview, but then in the seventeenth and more in the eighteenth century, the technical progress blessed Europe with telescope and a growth of mathematics. The conquest of the continents brought new knowledge about the earth. The question for the right dimension and the shape of the earth moved into the center of the scientific research. Since the angular measurement succeeded to feature a considerable accuracy, the measurement of length was the biggest problem for 200 years (Torge 2009).

The geodetic science succeeded to improve the determination of the dimension of the earth by long triangulation chains along the several meridians on the northern and southern hemisphere. The determination of the International Meter was more or less a by-product. On the basis of this and the expansive surveying methods, the European governments had new tools to manage the countries in a just way. The national economies were able to flower out in an unimagined way.

This deconvolution was a precondition for the preeminence of the European nations in the world. The implemented techniques gave distinction to the scientific specialization under the name of

“geodesy.” The application of the methods in small-scale areas of about less than 1 km^2 , in which the spatial discrepancies are negligible to small for a sufficient accuracy (Kahmen 2005), coined the profession of the “geometer,” later referred to as “surveying engineer”.

Whereas the systems of base mapping – big or small – got a national character, because the military security asked for that, geodetic technology always had to be international. Only with international cooperation and in addition with the cooperation with the neighbored geosciences, the possibility evolved for tackling the phenomenon “earth” (Ledersteger 1969) (Fig. 1). And all the more so when the scientific progress bestowed methods on us which could determine the gravity field, the rotation of the earth, the movements of the continents, and the mass movements of the earth’s interior (Fig. 2).

To determine the geodetic frame for national control networks was always one of the most important tasks of geodesy. But international cooperation on this became more and more successful (Schuster 2005). The International Earth Rotation and Reference Systems Service (IERS) maintains the International Terrestrial Reference System (ITRS), which describes the procedures for creating reference frames suitable for use with measurements on or near the earth’s surface. This International Terrestrial Reference Frame consists of the high-precision coordinates and velocities of about 400 globally distributed stations (Fig. 3). These three-dimensional Cartesian coordinates and velocities define the positions and the plate tectonic movement, the ITRS.

The ITRF points are part of the European ETRF and the regional networks like the German control net, called DREF, or even networks of lower order under national control; they form together the international frame of high precision. It makes us measure the dislocations of the 19 tectonic plates (Fig. 4), (Sella et al. 2011).

From the beginning astronomical geodesy was necessary to locate the datum of every triangulation net on the ellipsoid. Soon satellite orbits were calculated, and the theoretical earth tides were compared with those measured by gravimeters and horizontal pendulums. Insofar geodesy was

Geodesy, Fig. 1 The earth as a mathematical abstraction

Geodesy, Fig. 2 Study object earth

prepared for the huge next step, the use of the earth near satellites. Up to that time, the meteorological conditions only were disruptive elements for the optical determination of lengths and heights, but then the meteorological surroundings more and more came into view with the higher accuracy of all results.

Geodetic measures are deeply influenced by the shift of masses (Fig. 5) between tectonic plates and the respective interdependence with solid earth and oceans, atmosphere, hydrosphere, cryosphere, biosphere, and asthenosphere (universe). The scientific picture of the earth changed from the spherical shape of the spheroid to the ellipsoid, further to the

Geodesy, Fig. 3 The shape of the earth – under control (Courtesy to Prof. Harald Schuh, GFZ Potsdam)

Geodesy, Fig. 4 Tectonic plate dislocations (ITRS Combination Centre at DGFI-TUM 2014) <https://www.dgfi.tum.de/international-services/itrs-combination-centre/>

geoid. In addition the geodetic science taught us that our earth is in an ongoing process of change.

Today, the highly accurate geodetic frames ITRF and ETRF and the national frames like DREF are combined, even merged. Everybody

can locate himself or move in that system. His measurements – mounted in the net – are now worldwide identifiable for about better than 1 [cm] (Seitz et al. 2016). Unlike earlier times the surveying engineer can detect, if the sunspot

Geodesy, Fig. 5

Opposing forcing affecting the earth (Vienna University of Technology)

activity is strong and the magnetic field is jammed. This he has to take care of when performing his measurements.

Individual Property Rights

During the colonization of earth, people became increasingly aware that fruitful land is a scarce resource. It is worth to settle there and to assert the ground. On those places, where people met for trade and change, regulations were accepted for the peaceful way of dealing with each other. Not mentioning the tremendous achievements of the Romans in surveying of their empire, the geodesy steps into the limelight of history, when the harvest tax systematically turned to ground tax. At the end of the eighteenth century, the science provided the technological possibility to expanse scalable maps over the country and to document securely the property borders (Fig. 6). Since that time a fair, area-based tax regime became possible. Tax cadastres became fashionable for modern states. Soon large-scale soil fertility evaluation systems for farmland were set up on these cadastres.

The systematization of the taxation (Fig. 7) and the spread over the countries took technically and politically nearly a century in Europe. But this installation provided the nations with safe funds (Fig. 8). The other side of the coin was that the citizen's rights in their property were

strengthened. Geodetic technique was weaved in the deploying civil system of justice. The civil code, the land register ordinance, and the official regulations for the property cadastre came to their heyday at the beginning of the twentieth century. The taxable value is a legal definition for private plots, operational premises, and farming or forestry property. It should be equivalent to the market value, but all over Europe, there is a great variety of tax procedures and level of taxation. In countries like the Netherlands and Sweden, the method of mass evaluation for the ground taxation is discussed. A lot of member states of the European Union are seeking for an easy and secure way for this taxation. The qualitative classification of the nations concerning just ground tax, secure property, and successful mortgaging is an unmistakable sign for the development of land management.

The development did not come to halt (beside the communistic part of the world). Legal and management principles changed with the development of the economy and its regulations. The improved cartography and copying techniques lead to further cadastres showing other attributes of parcels and their buildings (i.e., cadastre on public land charges or pollution suspicion cadastre, geothermal cadastre, ao). They influence the rights in land substantially.

The geodetic professionals working in private or public businesses managed the property

Geodesy, Fig. 6 Modern cadastral map, 1:1000

cadastre and taxation in form of cadastre measurements and cadastre amendments and the evaluation of the ground (Schuster 1981).

In the nineteenth and twentieth century, the rural and urban land readjustment and the management of settlement became an important economic factor driven by geodetic professionals. With the measures of public authorities, the farmers succeeded to raise their crop yields substantially; the drift of the population to the cities was stopped. They succeeded to overcome the big streams of people into the industrial areas.

At least after the Second World War, they managed to integrate 12 million people into the West German population. Geodetic reallocation and evaluation measures were a significant part of the success.

Real Estate Economy

Geodesy is a basis for all real estate economy.

The upcoming time of geo-information opens new economic prospects and effective tools for the protection of our environment. The safe governmental documentation of properties and the loan capabilities (Kerl and Schuster 2003) provided the growing economy by capital generation. The results are reflected in a growing built-up space for industry and residence. Diverse forms of right or property were developed on the basis of the property register and cadastre. They developed their own business cycles. Geodetic services were part of this process of development, but managed mostly only the geometric relocation of the property borders. Slowly they supplied the growing demand of their clients in consulting concerning the more and more complex subject.

In the socialist countries, this development failed even if the geodetic basics and also services for mapping and the building regulations were still or even newly existing. Without the individual property in land, the economic shaping forces were lame. The real estate economy was no area

Geodesy, Fig. 7 Soil fertility valuation, 1:5000

Geodesy, Fig. 8 Soil fertility map, 1:2000

of added value. After the political transformation in 1989, this form of economy on the basis of land quickly induced a takeoff. The authorities quickly transformed their character and got reformed. But

with these events, the societal questions around land are not yet answered. The more developed a nation and its civil class is, the more sophisticated and dense is the wood of regulations based on

land. This business life pushes the gross national product of a country immensely. But in that sphere, there is easily coming up the danger of non-genuine growth: economic blows and the growth of bureaucracy can jeopardize the national economy. Both emerge because of inappropriate regulations and misguided public work.

Geodesy is part of this economic process by its land management component, which expanded its methods and performance strongly in the second half of the twentieth century. The German federal building law (BauGB) and the federal land use order (BauNVO) together with the rapidly growing public law considerably influenced the methods of property evaluation and readjustment, which were used in the public and private part of the business life. Other developed countries have similar regulations.

The development of standard ground values and the installation of committees of expert valuers became an internationally acclaimed model for subduing the blows or deflation elements.

Since the Millennium not only the migration from country to town was noticeable but also the diminishing of an aging European population becomes apparent. The economic output of the house construction industry became much smaller and this happened as well in that part of the geodetic economy. On the other hand, the investments for the maintenance and renewal of the buildings pushed ahead by certain tax reductions and ecological regulations grew strongly. The industry sold their houses for workers by privatization, so the number of transactions swelled (Fig. 9). The people as economic actors wish to safeguard their property, and by that the economic transactions remained on a high level.

Foreign capital searched from 2005 to 2008 for investment opportunities. This pushed the price level especially in the European agglomeration zones. Geodetic services are involved in that part of the economy with evaluation of real estate, property consulting, and evaluation for mortgages.

These different types of propulsions let the transaction traffic remain on a high level, even if the development of new development in unbuilt areas was strongly reduced.

Geodesy, Fig. 9 Numbers of transactions – city of Duisburg

Geodesy, Fig. 10 Cash flows of transactions – city of Duisburg

From both pictures (Figs. 9 and 10), you can deduce the economic importance of the real estate economy. In a city of 500.000 inhabitants happen to be concluded not more than about 4000 contracts per year, which means not more than about 8.000 contract parties. It is a small part of the town's people to exchange a fortune of 500 Mio € up to 1 billion € per year. A number of 250–500

unbuilt plots with a transaction value of 50 to 80 Mio € changed the ownership. These plots are predominantly the basis of a development of the city further on.

The number of contracts for developed, built plots is about 1.500; their value balances around 500 Mio €.

1200 to 1500 contracts are concluded concerning residence and part ownership with a value of about 60 Mio €.

Behind the curtain of this development, over the years there are a lot of different influences changing from year to year. The last ascent of values is reckoned to be based on the fear of people for their financial assets, not coming from a bigger need on the renter's side.

From "concrete gold" people expect to gain the best long-term maintenance of value.

Market economy is a contract economy. The exchange of property only means the top of the economic contracts in the real estate economy. The broad base of contracts is the renting contracts.

An exchange by contract of about one billion € releases work for the service institutions register and cadastral office, notary, broker, and public appointed surveyor of about 50 Mio €. The

transaction tax for the community as well costs the parties 5% which means about 50 Mio €.

Geodetic Technology

Geodetic technology is more productive than ever in history (Schuster 1985). The number of sensors and items grew enormously: satellites for GNSS, altimetry, gravity field missions, side-looking airborne radar (SLAR) or synthetic aperture radar (SAR), and Doppler Orbitography and Radio-positioning Integrated by Satellite (DORIS) (Fig. 11). Not to forget the equipment for atmospheric exploration, the Very Long Baseline Interferometry (VLBI) and the tide gauges or even complex systems like tsunami detectors are all being used in the low and medium earth orbits.

With remote sensing a new geodetic technique came up for evaluation of the satellite photography, laser and radar surveys.

New sensor technology presents a variety of technical devices with regional impact like surveying planes or helicopters, steered by IMUs (inertial measurement units) with a variety of aircraft cameras and lasers. Most of the sensors built have a local impact: GNSS Rovers for dm

Geodesy, Fig. 11 Geodetic technology in the earth near space (Courtesy to Prof. Harald Schuh, GFZ Potsdam)

Geodesy, Fig. 12 Geodetic sensors with local perimeter

or cm – accuracy, combined positioning and sensor systems for vehicle fleets or personal tracking as well as tachymeters as total stations and laser scanners of different type (Fig. 12).

In the metrological scale, we find many robotics and high-precision measuring instruments (laser tracker *ao*), necessary for 3D measurements, and in-house laser systems in a local reference system.

The geodetic methods are directed upon maps and scientific results, but also upon data pools consisting of maps and alphanumeric information like property cadastre and surveying and engineering geodesy. They are used for the control of the building process. There is a big variety of procedures, products, and results. As far as they are based on measurements, they are to be distinguished by an implicit or explicit stochastic. For long the maps developed to graphic interactive systems (GIS). The orthophoto as an automatically generated aerial scalable photo is a worldwide proven and successful product.

Unexpectedly the unmanned aerial vehicle (UAV) or shortly drone started its triumphal march into the geodetic technology: equipped with cameras of most different quality or even small lasers, they catch up the objects in the space near to the surface (Haala and Schwieger 2017). The point clouds produced lead to new economic useful results, i.e., for monitoring, quantity or mass calculation, urban models of

higher level of detail (LOD), roof landscapes as orthophotos (Fig. 13), a geodetic base for the building information modeling (BIM), or disaster control. Powerful geodetic software modulates the transformation of the point clouds.

Geodetic laser scan or even laser slam methods (without any fixed standpoint) capture new fields of application spirited up by the revolutionary building information models, which need and are able to process Big Data results during the construction process (Fig. 14).

Parallel to mechanical engineering, the quick comparison between the actual status of a construction in progress can be realized with an authentic point cloud by laser slam, which is called “trusted living point cloud” (Fig. 15).

The actual expansion of the sensor technology and the velocity of the data capturing enable the geodesy to do its bit for the “smart construction site.” The cross-linking of sensors, devices, machines, and finally the workforces is beginning (Fig. 16). The result is a seamless communication between sensors and server over the Internet. The sensors deliver the current necessary information for workforce and fleet management and support the accounting of the site’s activities. Complex algorithms and modern mathematical filter methods have to be composed.

Inertial measurement units (IMUs) in connection with great effort in terms of data filtering will play a great role in the future geodetic technology,

Geodesy, Fig. 13 Roof landscape as an orthophoto (acc. $<\pm 1$ mm) captured by UAV

because they are able to fix the coordinates of a moving object down to [mm] accuracy together with GNSS as a frame. So the coordinates of any moving object can be created coincidentally. One scientific challenge of the hour is the high-precision time adjustment of the different moving sensors.

The New Age of Geo-Information

Geodesy means basically the technique, which connects freely selected points with an imaginary line. This technique got social and economic importance with the property cadastre. The border points were surveyed, and the imaginary line between them was the property boundary. It is the borderline between the spheres of activity between neighbors. These borderlines are the most important legal and economic reference frame (Schuster 1997). Most of the authoritative actions and private measures relate to that system. Coordinate systems – as described above – are from that view auxiliary systems, which ease to comprehend the economic life.

Two hundred years ago, the installation of such a reference system “property borders” needed a huge economic effort of the authority. Today, the sum of new technologies enables the geodetic community to give a coordinate to all points, on

Geodesy, Fig. 14 Building captured by laser slam – base for BIM

which the society wants to imprint its will. Since that procedure happens quickly, the movement of objects or even that of men can be documented in such coordinate systems.

Vice versa every coordinate created bears a certain information, the geo-information (3. Geofortschrittsbericht der Bundesregierung 2012).

Seen from an economic viewpoint, the elements of the unnumbered nature and that of human privacy become finite-measurable. This means that water, air, wood, etc. a hundred years

meta-levels are needed, which means the graphic design in gliding scales and gliding adapted degree of abstraction.

Meta-data as well mean numerical description, the naming of maps and the description of the accuracy of the coordinates or related structures.

The public authorities gain a lot of advantages for their work on future topics like climate, energy, mobility, sustainability, and demographics. The European authorities started early with INSPIRE and Copernicus (former GMES) (Alessandro and Claude 1999). On national and regional level, the European structure got sub-structures (i.e., GDI-DE) partitioned to responsibilities.

The INSPIRE directive gives the legal frame for that Europe-wide geo-data infrastructure.

Worldwide suppliers of geo-information like Google or Microsoft today seem to be unavoidable, and they disperse in the economy with new business models (Barwinski and Schuster 1988; Schuster 1997).

Discussing the naming of this new field of work, international groups decided to change the

term to “geomatic” to show that the geodesy has expanded its field.

Geodesy as an Economic Sector

It is comparatively simple to value the costs of an economic sector on the European continent, because the professionals remain for a very high percentage of their professional life in their profession once chosen.

The “Market Report” presented by the Comité de Liaison des Géomètres (CLGE) and Geometer Europas (GE) (Schuster et al. 2003) comes to the conclusion that the volume of costs, deduced from the salary payments to geodetic professionals in the year 2000, is about 24 billion €. This sum comprises those who are busy with the maintenance of the public property system and public maps as public servants, as well as those who are active in the private business life in form of surveying, evaluation, and software (Schuster 2003).

Given that the predominant part of demand in geodesy is due to the building applications, Fig. 17 shows the dramatic changes in demand

Geodesy, Fig. 17 Dramatic changes of supply and demand

since the 1950s and the steadily growing number of supply (number of private offices) in a state like North Rhine-Westphalia with about 18 Mio inhabitants.

The private service structure of the supply answered with the reduction of personnel and an furthermore improved its offering with better quality of comprehensive services on the basis of the extending public regulations; the public structure passed several waves of reorganization but benefitted from the extending relevant legislation.

So, the demand for geodetic supply is relevant to the legal situation of land as a whole. The differences between countries can be huge.

In a developed country like the Netherlands, the geodetic community speaks about “crowdsourcing,” which means that the owners themselves are able to identify the property boundaries between their parcels on the basis of a well-explained cadastral information of the public authority.

The Internet now has brought up a new situation, where some hundred experts, i.e., from Google and Bing, can theoretically reach the whole mankind with their products. The funds for this investment and its maintenance come mostly from sources outside of the professional sphere (i.e., marketing). The underlying business model couples different sectors, which is not unusual in the economy (Schuster 2004).

Whereas the old business model of the geodesy was relatively closed and strongly regulated and could be broken down into

- Public mapping
- Maintenance of cadastre
- Cadastral surveys
- Sequent control of building geometry,

the business field expanded its supply strongly by the vast new field of sensors, the practically unlimited possibility for the geo-referencing of any object, and the use of the Internet. The enlargement of the supply is financed in the middle-class economy by the old business, big public investments, and the hope, which was induced by the technological progress. The

demand is lagging behind, which means generally low prices for the services.

The situation in various European countries is different, and it is scarcely straightforward because of the degree of regulation, not to mention the clearness in detail. Beside such difficulties one can say that the old geodetic business model was pillared by:

- Ground tax
- Transaction traffic
- Settlements
- Military needs
- Sequent control of building geometry

Nowadays is upcoming a growing income for the use of most different geo-information. One quickly spreading example is the area cadastre. With this GIS the communities are able to split the fees for percolation water and sewage. New services are created. With the cadastre of trees, of greens, and of public easements, they help to manage the real estates and have an organizational added value.

Many people look forward to a growing activity in geodesy. But the answer to the question is not yet clear, until new “biting” business models and broader economic trends will show up. Undoubtedly, they will deform the old economic basis.

Geographical Indications

Marco Ricolfi

Department of Legal Studies, Department of Law,
Turin University, Turin, Italy

Definition

The issues at hand. Geographical indications (GIs) are signs (or symbols) used in connection with the sale of goods which convey an association, direct or indirect, with a place or location, which may be relevant for certain features of the good in question.

Rules concerning GIs may be found both at the municipal (or domestic) level and in international agreements. The international framework for dealing with GIs is to be found in the 1883 Paris Convention, in the 1891 Madrid Arrangement and in the 1958 Lisbon agreement. After the adoption by the European Union of the *sui generis* regime for GIs and designations of origin in 1992, a multilateral equilibrium was found in the 1994 TRIPs agreement.

When the same geographical symbol is used simultaneously by many businesses, a number of issues arise which may be dealt with in several ways. The different alternatives are discussed hereafter along with the reasons which may dictate the choice among them. They all rely, however, on a common assumption: that GIs should, at least in principle, not be appropriated by one single business at the expense of all its rivals. Therefore, we first deal with this assumption, which is shared by most legal systems.

Geographical Symbols and Individual Trademarks

Most legal systems prevent a single business to register as a trademark a geographical symbol (or to otherwise obtain exclusive legal rights over it). The reason for this prohibition is straightforward and has two prongs. Let us assume that the business trying to appropriate the geographical symbol is in fact established in the geographical area to which the symbol alludes to. If this is the case, and the geographical origin is responsible for features which are relevant for consumers' choices, then the grant of a trademark registration would generate an unwarranted competitive advantage for the benefit of one business to the exclusion and detriment of all its competitors. The matter gets even worse if we consider the second prong: if the business holding the trademark is not even located in the geographical area to which the symbol alludes and, therefore, the goods originating from it do not possess the corresponding features, then the public is deceived.

Usually, these difficulties are tackled by four related rules:

- There is a bar on the registration of signs which convey an association between features of the good and a given place (in US law: primarily geographically descriptive symbols).
- Should in fact the goods bearing the trademark in violation of the previous rule also come from an area different from the one designated by the symbol, this would also amount to prohibited deceptive behavior.
- However, the two rules above do not prevent the registration of a geographical symbol which, on its face, has no association whatsoever with features of the goods on which it is affixed; Montblanc fountain pens is a good example of this situation.
- Also, in some – but not in all – legal systems registrability may be obtained through the acquisition of a “secondary meaning,” which, in this case, indicates that the relevant public no longer associates the indication with a geographical place but with a business origin which has obtained recognition in the marketplace.

One Geographical Symbol, Many Users: The Legal Options

All the difficulties associated with the use of a geographical symbol, discussed in the previous paragraph, fade away when the geographical symbol is used simultaneously by several businesses, all located in the area which is relevant for the characteristics of the goods. This is an occurrence which is more frequent in connection with agricultural goods, such as wines, cheese, fruit, and the like, but may occasionally be relevant also for manufactured goods which embody handicraft traditions, such as pottery and fabrics (Cuccia and Santagata 2004). This does not mean that the simultaneous use of the same geographical indication by different businesses is unproblematic. To the contrary, this situation may generate a number of difficulties, which, while different from the ones arising from the use by a single business, still require the adoption of appropriate legal devices to avoid the emergence of recurring shortcomings, which include consumer deception

and unwarranted competitive advantage, again, but are not limited to them.

Three are the main options available to deal with the issues arising by the use of geographical symbols by multiple businesses, which may consist in the setting up of property rights, in the resort to liability rules, and in the adoption of a *sui generis* regime. While the choice between these different options ultimately rests on international considerations, rather than on the comparative assessment of the economic costs and benefits of the different approaches, for analytical reasons we will first describe the different options available at the domestic level in an economic analysis of law (EAL) perspective, reserving for a later stage consideration of the international factors which determine the choice.

The Domestic Level: Property Rights

It is possible to set up property rights enabling multiple businesses to use the same geographical symbol in a coordinated and nondeceptive manner in two different ways: collective trademarks and certification marks. Both are known in common law systems as well as in civil law countries. However, the latter tend to favor collective trademarks, the former certification marks (Belson 2002; on the status of collective and certification trademarks in the TRIPs Agreement see Pires de Carvalho 2006; on the corresponding notions Spada 1996). In either case, the geographical sign is registered as a trademark; as a result, any use by an unauthorized third party of a sign which is identical or similar for the goods indicated in the certificate is automatically considered as an infringement.

What distinguishes collective and certification trademarks is that in the former, the holder of the trademark is an entity (a corporation, a consortium, an association) and the users are members of the same; in the latter, the holder of the trademark is an independent third party, with no links with the users, which is legally prevented from engaging in the business for which the trademark is registered. This third party is contractually

bound to certify that users comply with the applicable standards, as agreed in an appropriate document (the “specification”).

In short, collective trademarks are membership-based; certification trademarks are contract-based. All the differences in the rules concerning collective and certification trademarks flow directly from this distinguishing feature.

Collective Trademarks

Each user obtains authority from the entity which holds the trademark to use it in conformity with the “specification,” which is adopted and submitted with the application for registration. In principle, only businesses which are members of the entity holding the registration are allowed to use the collective trademark. On the one hand, this rule is consistent with the more communitarian underpinnings of collective trademarks: only businesses which operate in the geographical area which is relevant for the features of the goods or otherwise share a characteristic which is signaled by the collective trademark are allowed to resort to it. On the other hand, making membership of the trademark-holding entity a precondition for use entails the possibility of abuse. More specifically, the risk is recurring that businesses complying with all the requirements are denied the opportunity to become members of the collective trademark holding entity and therefore to obtain a license to use it. Legal systems tackle this risk in several ways (Sarti 2011; Spada 1996). In some systems, an “open door” policy is mandated: applications for registration of collective trademarks are granted only on condition that the by-laws of the applicant entity provide that each business meeting the requirements is allowed to become a member and to obtain a license to use. In other systems, even non-members are entitled by law to use the geographical indication corresponding to the collective trademark, provided the sign is used as a descriptor of geographical origin rather than as trademark. Legal systems which do not adopt these approaches may resort to antitrust laws to make sure that the denial of admission to membership of a business meeting all requirements is prevented.

Certification Trademarks

The entity holding the certification trademark may be public or private and may come in any legal form. What is of essence is that its relationship with users is contract-based: compliance with rules set in the specification entitles to use of the trademark; no discrimination is allowed in the certification. This is the rational basis of the rule whereby the certifying entity may not be in the business sector for which it gives the certification.

The Domestic Level: Tort

Businesses located in a certain area which is relevant for some of the features of the goods they supply have not only the option to obtain a property right in the geographical indication, but, as an alternative, they may also resort to tort law. This is particularly so in legal systems which give protection against unfair competition. However, the scope of protection afforded under liability rules is more limited than the one based on property rules. A predicate required before a business operating in the relevant area may claim protection against use by a third party to associate with the location is that the geographical sign has already reached a certain degree of recognition or reputation. It should be noted in this connection that, when protection is sought at the international level, recognition in the country of destination (import), not of origin (export), is controlling. The businesses operating in the relevant area must also prove that the third party resorting to the corresponding geographical symbol is taking advantage of a reputation it has not earned (“free ride”), to the detriment of lawful users (“injury”) and, additionally, that the public is likely to be deceived. This requirement entails another limitation in protection; disclaimers, such as corrective additions on the label (e.g., Roquefort, produced in Ontario, Canada) or qualifying language (e.g., Roquefort-type), may avert liability.

A Comparative Assessment

There is not much literature comparing the costs and benefits of protection of GIs under property

rules as opposed to liability rules. This is rather unsurprising, as the protection of GIs is not prevailing in the Anglo-Saxon world (Faulhaber 2005), and European scholars are wary of treading in waters not tested by American literature (Ricolfi 2009a). However, in a welfare maximization perspective, we may quite safely assume that the property and liability rules are effective in a roughly equivalent way in pursuing the goal of lowering consumer search costs. As to the other function of trademarks, to provide an incentive to invest in quality (or, rather, a combination of quality and price which meets consumers' desires), it is submitted that, on the one hand, property rules tend to be superior. Resort to a standard set by the relevant community in a formal and transparent way, the specification, is likely to avert resort to free-riding better than a reference to more nebulous "best practices" to be established during litigation. However, the costs of setting up a collective trademark registration system are likely to be substantial (Van Caenegem 2004). On the other hand, assuming that adjustment over time is a desirable feature for GIs, where standards may change over time, it is arguable that tort-based systems are superior to property-based systems, as they tend to be more flexible. This is so because they rely on the understanding associated with a specific geographical symbol at the time a controversy arises rather than on the notion codified once and for all in a specification.

The Sui Generis Regime of Protection of Geographical Indications

In the quest for protection of geographical symbols, there is a third alternative which tops the property and liability rules-based systems just sketched out: the *sui generis* regime adopted back in 1992 by the EU, which is remarkable in itself and as an (alleged) blueprint for the multi-lateral provisions adopted by Artt. 22 ff. TRIPs. The current version of the EU regime is to be found in reg. no. 1151/2012. All in all, this regime is more similar to property than to liability rules-based systems, even though it deviates from them in that there is no person or entity which may be

described as the owner or holder of a sign. The collective monopoly, bestowed on all businesses which can show their location in the relevant area and compliance with the requirements set by the specification, is the result of a public law proceeding initiated at the local level and completed by the grant of title by the EU Commission. What is provided by this set of rules is a *sui generis* regime, characterized by low access requirements and strong levels of protection. This feature is not very usual in intellectual property law, where, by and large, the level of protection is commensurate to the access requirement. The deviation shown by the EU *sui generis* regime is accounted for by a clear political choice intended to give a high level of protection to agricultural communities and to their local traditions in growing and producing foodstuffs.

Three components of the regime stand out.

1. As far as *access requirements* are concerned, the regime, Art. 5 of reg. no. 1151/12, applies to so-called protected designation of origin (PDO) which, as in the prior international framework, refers to signs identifying products whose quality or characteristics are essentially or exclusively due to a particular geographical environment with its inherent natural and human factors (the so-called *milieu*). The protection extends, however, also to "protected geographical indications" (PGI), the requirement for which are remarkably lower as they depend not on objective criteria (the *milieu*) but on the subjective factor of the reputation and even admit to some relaxation as to the localization of the production steps;
2. While in theory "generic terms shall not be registered" as PDOs or PGIs, Art. 6 of reg. no. 1151/12, in practice even descriptive terms, like "Feta," for the characteristic cheese of Greek origin, have been found to be registrable even though they had been in common usage outside Greece for long time (the ruling by the European Court of Justice was adopted in 2005). Under Art. 13 PDOs and PGIs, once registered, are no longer subject to genericization.
3. Registration as PDO or PGI confers an exclusivity over the sign entailing very strong

protection. While the protection for ordinary trademarks is granted only against the risk of confusion, here the grant extends to usage which falls short of such a risk (e.g., mere “evocation”) and does not take into account the presence of disclaimers which may prevent consumers’ confusion (Art. 13 of reg. no. 1151/12).

Originally the *sui generis* regime was thought of as a tool to facilitate the replacement of member States rules by a single EU protection title. However, Art. 11 of the current regulation opens up access to this EU title also to non-EU entities, in furtherance of the TRIPs-mandated prohibition of discrimination against non-EU nationals.

The comparative assessment carried out above may be extended to the *sui generis* regime. Overall, the regime is closer to property than to tort: access requires registration; once registration is obtained, no proof of deception of the public or of injury to lawful users is required. What is remarkable in the regime is the political nature of the process which leads to the registration. For example: one single Greek island may register a dozen GIs for olives and oil, not so much because there is a business rationale for this proliferation but because local politicians and communities choose to engage in an exercise where most of the costs are borne by the general taxpayer. This is hardly surprising: a preferential treatment for agricultural communities is at the basis of the French-German alliance which has been underpinning the design of the EU from its beginnings.

The International Level

One might assume that lawmakers are in a position to choose among the options described in above in order to maximize the welfare of their constituency and that they accordingly proceed to select the regime which minimizes costs and maximizes the benefits. In real life, lawmakers have another, overriding variable to consider: the position in international trade of the political entity they are legislating for. In this connection, two

considerations should be factored in. *First*, the choice has a very strong mercantilist component: usually countries tend to support exports and discourage imports; and this applies also to goods bearing geographical indications. In this regard, producers’ interests may prevail over consumers’, as predicted by collective action theory. *Second*, goods originating from a given country (country A) may derive competitive advantage (or disadvantage) not so much from rules adopted in country A as from rules applicable in the export markets countries B, C, ... N. As a result, it is submitted that, while EAL is a powerful analytical tool to examine the competitive consequences of the different options, it is public choice theory which ultimately accounts for the choice among the various options.

This is the backdrop against which the international framework of norms concerning GIs has to be assessed. In doing so, one should never forget that here we are dealing with power structures rather than with economic optimality.

The 1891 Madrid Agreement: The Tort-Based Approach The 1883 Paris Convention, which is considered – along with the 1886 Berne Convention for copyright – as one of the two pillars of international intellectual property protection, only mentioned geographical indications without adopting specific rules concerning them. As a follow-up to it, the 1891 Madrid Agreement was adopted, which visualized protection of GIs as an issue of unfair competition. Access requirements for protection are low. Also simple (and indirect) indications of geographical origin are protected; therefore no specific link between the features and the place of origin is required. Correspondingly, protection is weak: it is confined to cases of actual fraud; even more to the point, the relevant recognition and reputation of the goods designated by a geographical indication has to be established on the sales market, not in the country of origin. In this perspective, the Madrid rules are acceptable to countries which tend to import, rather than to export, goods bearing GIs.

The 1958 Lisbon Agreement for the Protection of Appellations of Origin The countries which

tend to export, rather than to import, goods bearing a geographical indication pushed in the opposite direction half a century later, finally adopting the Lisbon Agreement in 1958. This convention presents features which are the obverse of the ones observed in the Madrid Agreement. The access requirements for protection are high: only signs identifying products, the quality or characteristics of which are exclusively due to the *milieu*, are eligible and their protection is contingent on registration in appropriate national registers. The scope of protection is correspondingly high: it extends to usurpation and imitation; infringement is not ruled out by disclaimers or rectifying language (e.g., “like” or “type”); and, most importantly, it has an extraterritorial dimension, in that, once the appellation of origin is registered in one State party to the Agreement, protection extends to all the other States automatically, without the need to establish either recognition or reputation on the sales market.

The problem with the Lisbon Agreement is that it only includes like-minded countries. The 27 States which are parties to it are notable for the importance and quality of their agricultural production, which makes them export-, rather than import-oriented. For their own part, import-oriented jurisdictions are loath to join an agreement which would increase the level of protection of foreign productions to the detriment of local businesses. In 2015, the Geneva Act has tried to take care of these difficulties, lowering the access requirements to the system. Whether this move will in fact enable the participant countries to reach the required critical mass remains to be seen.

A Half-Way House: The GI Provisions in TRIPS

EU officials like the idea that the TRIPs provisions concerning GIs (Artt. 22–24) follow the blueprint of the European *sui generis regime* (Gervais 1998). This is to a very large extent a delusion. While a regime resembling the EU approach is envisaged for wines and spirits (Art. 23), all other GIs are dealt with as a tort or unfair competition issue: no protection is available without deception of the public (Art. 22). As a result, the EU has placed itself into a situation where it is under the obligation to extend the benefits of its

generous *sui generis* regime to all businesses which are resident in a country which is a TRIPs member (Artt. 3–4) while its own businesses cannot claim a protection going beyond tort law for European GIs abroad, which was already available to them under the 1891 Madrid Agreement all the time. The EU appears all the more misguided as it tries to lure developing countries to follow it into a bargain in which it is a clear loser (Ricolfi 2009b).

Future Directions: Conflicting Agendas in GI Protection

There is no doubt that the EU and the Anglo-Saxon world are pushing in opposite directions as far as GIs are concerned (O’Connor 2004). The latter favors GI rules which avoid competitive disadvantage deriving from location for their powerful agro-businesses. The former extends into the twenty-first century the traditional pro-agricultural communities attitude inherited from the French-German arrangements at the basis of the European architecture. What we do not know as yet is how this divergence will fare when brought into the much wider compass of global competition. Initially, the rival views have played out in the bilateral and regional free-trade agreements (Rangel-Ortiz 2014). Until the US elections in 2016, it would have seemed that the American approach was taking the upper hand also in international trade negotiations, such as the Trans Pacific Partnership (TPP) and the Trans-Atlantic Trade and Investment Partnership (TTIP). However, the situation is very much in a state of flux now, as a result of the repudiation of these treaties by the Trump presidency.

We may wonder what role was – and is being – played by Economic Analysis of Law in the process. Perhaps unsurprisingly, EAL-based tools may contribute to understanding what are the costs and benefits of the different alternatives at hand, but as the choices are being taken at the super-national, rather than domestic level, they seem to be suggested much more by power dynamics rather than by the pursuit of welfare optimization.

German Law System

Sonja Elisabeth Haberl
University of Ferrara, Ferrara, Italy

Abstract

The following entry provides an overview of some elected aspects of the German law system. From different points of view, the German system has been deeply influenced by the ordoliberal ideas developed within the Freiburg School in the early 1930s of the twentieth century. One of the core ordoliberal concepts that have to be discussed within the constitutional framework is that of a social market economy. Social market economy became the interpretive framework for the economic and social order of Western Germany in the aftermath of World War II, and today, it represents not only a key concept at national level but also within the European Union. No less important is the role of the so-called Private Law Society, another key concept of ordoliberal thinking. Its main elements are clearly reflected in the *Bürgerliches Gesetzbuch* (BGB) of 1900 which is based on the idea of the citizen as a *homo oeconomicus*. Notwithstanding its traditional approach – libertarian, unsocial, and

individualistic – the BGB, a child of the abstract conceptualism of the Pandectist school, has been able to survive till today. This is the merit of judge-made law and, in particular, of the theory of the indirect horizontal effect of fundamental rights in relations governed by private law. In recent times, the BGB has even assumed a highly visible role as a possible model within the harmonization of European contract law. The entry finishes with a description of the German system of legal education, a state-oriented and judge-centered bureaucratic model which is still embedded in the model of a “uniform jurist,” the so-called *Einheitsjurist*.

The Constitutional Framework

The memory of the collapse of the ill-functioning, weak, and helpless Weimar democracy which facilitated the slide into a totalitarian dictatorship has profoundly influenced the framers elaborating the post-1945 constitutional order of a West German state (Kielmansegg 1990). The document which should offer appropriate guarantees for the development of a solid democracy, able to defend itself against its enemies, was elaborated by a Parliamentary Council, composed of 65 members elected by the state parliaments, and approved by the *Länder* rather than by popular referendum. It entered into force on 23 May 1949 and was named *Grundgesetz* (Basic Law) and not *Verfassung* (Constitution) in order to underline its provisional character while waiting for unification. Despite this, the Basic Law outgrew its temporary character by means of the accession of the five East German *Länder* to the FRG in October 1990, and with only a few provisions revised and others inserted, it became an all-German constitution within the new Berlin Republic.

The Discussions About the Basic Law’s Economic Order: Social State, Social Market Economy, and Ordoliberalism

Unlike the Weimar Constitution, the Basic Law does not contain any explicit reference to social

rights. The only indirect references are included in Art. 20, which defines Germany a “democratic and *social* federal state,” and in Art. 28 which requires the constitutional order in the *Länder* to conform “to the principles of a democratic and *social* state governed by the rule of law” (the so-called principle of homogeneity). The reasons for the mere affirmation of the social state principle are closely connected to the highly conflicting positions between the constitution-shaping political forces with regard to the economic order which the Grundgesetz should refer to. While the Social Democratic Party tried to promote the concept of economic democracy, based on a form of planned economy, workers’ participation in management, and the nationalization of important economic interests (Bommarius 2011), the Christian Democratic Party argued in favor of a system of neoliberal democracy, in which state intervention should be aimed at creating the necessary conditions for the functionality of the market mechanism. Since the various political forces involved in the constitution-making process were not able to reach a consensus on this issue, they set aside the prescription of a specific economic model in the Grundgesetz. As the Federal Constitutional Court later stated, the Basic Law is “neutral” as regards the economic order (4 BVerfGE 7 (1954)). Instead, they contented themselves with reference to the principle of the social state, thus giving rise to the paradoxical fact that the Basic Law ascribes a fundamental rank to “the social,” yet without defining it more precisely by means of specific social rights.

After a short time, a new key word was coined through which the task of the German State to perform as a “social state” should be fulfilled (Zacher 1987): the ideas underlying the concept of a social market economy are theoretically and ideologically deeply rooted in the ordoliberal ideas developed within the Freiburg School during the Nazi dictatorship. In harsh opposition to the Weimar party and intervention state (Stolleis 2002), its proponents – among others the economists Eucken, Rüstow, Röpke, and the lawyer Böhm – were united in the idea of militating against social and political pluralism and arguing in favor of a “strong state,” called to efficiently

manage the economy by building and enforcing a legal regime representing an *ordo* intrinsic to economic life (Joerges and Roedl 2004). The ordoliberals thus propagated the so-called third way as the proper alternative between laissez-faire liberalism and collectivist forms of political economy, calling for the establishment of a system of undistorted competition in order to enhance the functioning of the economic order.

It was Alfred Müller-Armack who substantiated the ordoliberal ideas in the enticing slogan social market economy and transformed it into policy together with Ludwig Erhard under the chancellorship of Konrad Adenauer. Social market economy refers to a strategy based on voluntary market transactions with undistorted competition and private law mechanisms as its fundamental elements, to be complemented only by a certain kind of state intervention: contrary to what one could think, in fact, the meaning of the attribute “social” does not refer to a policy of social justice associated with a welfare state. Müller-Armack, by arguing for the “total mobilisation of all forces” (Müller Armack 1933), to be achieved by enabling individuals as self-responsible and self-determined entrepreneurs (Bonefeld 2012; Somma 2013), primarily referred to the efficiency of a market economy, i.e., to the fact that the latter generates economic growth and wealth, thus directly and automatically bringing about social achievements (Joerges and Roedl 2004). In addition, he required “a system of social and societal measures” as social peacekeeping tools which however had to be *marktkonform*, i.e., consistent with the competitive order (Müller-Armack 1966).

Social market economy has become a core concept of the foundational period of the FRG, whose success story in the postwar period is frequently associated with it. With its insertion, in 1990, into the treaty establishing a Monetary, Economic, and Social Union between the FRG and the GDR, the term achieved the rank of a legal norm for the first time. It is also included in the Treaty of the European Union (Art. 3) which sets among its objectives that of a “highly competitive social market economy.”

The System of Fundamental Rights and the Bundesverfassungsgericht as the Guardian of the Grundgesetz

The outstanding importance of the fundamental rights included in the *Grundgesetz* is emphasized by their location – they are all placed at the head of the document (Arts. 1–19), with the guarantee of human dignity at its core. In the words of the Federal Constitutional Court (Bundesverfassungsgericht), the paramount importance of Article 1 par. 1 – which declares human dignity as inviolable and provides for its obligatory respect and protection by all state authorities – can be explained only by the historical experience and spiritual-moral confrontation with the previous system of National Socialism. In order to avoid another abyss, the *Grundgesetz* has constructed a “value-bound order in which the individual person and his/her dignity is placed at the center of all its rules and regulations” (39 BVerfGE 1 (1975)). Art. 1 par. 1 thus expresses the highest value of the *Grundgesetz*, which not only has an effect on the following fundamental rights but also informs the substance and spirit of the entire document (Häberle 1987).

The whole system and structure for the protection of fundamental rights aim to correct the mistakes of the past. While the fundamental rights included in the Weimar Constitution were only declaratory and thus not judicially enforceable, the Basic Law’s fundamental rights are transformed in subjective rights by Art. 1 par. 3 which states that they “shall bind the legislature, the executive and the judiciary as directly applicable law.” In addition and also directed at remedying the deficiencies of the Weimar Constitution, the *Grundgesetz* contains precise rules and limits which have to be respected in the context of the restriction of a fundamental right, whose “essential core” (*Wesensgehalt*) may in no case be infringed (Art. 19).

On the other hand, the *Grundgesetz* provides for the forfeiture of certain fundamental rights, should they be abused “in order to combat the free democratic basic order” (Art. 18). Besides the possibility of a party ban (Art. 21) and the

prohibition of associations (Art. 9), the forfeiture of basic rights is considered to be one of the core elements regarding the conception of democracy in the Basic Law, qualified as a “militant democracy” (*streitbare oder wehrhafte Demokratie*), which “expects its citizens to defend the free democratic basic order and does not accept the misuse of fundamental rights aiming to undermine it” (28 BVerfGE 36 (1970)). In order to further strengthen this concept, the Parliamentary Council opted for the textual anchoring of a so-called eternity clause (*Ewigkeitsklausel*) according to which certain core elements of the Constitution are unamendable (Art. 79). The federal state principle, human dignity, and the basic principles of state order mentioned in Art. 20 belong to the elements which represent the identity of the Basic Law and are thus immune to any constitutional revision.

The supreme guardian of the Constitution is the Bundesverfassungsgericht (BVerfG). It was established in 1951 and is vested with extraordinary powers. It has not only the competence for constitutional disputes between federal organs and between the federation and the *Länder* but also the right to control the constitutionality of laws and to deal with individual constitutional complaints which can be initiated by a person who alleges to be negatively affected in his/her fundamental rights by an action of the public authority. The proceedings for controlling the constitutionality of laws can either be initiated by an ordinary court (concrete judicial review) or upon application of the Federal Government, a *Land* government, or one fourth of the members of the *Bundestag* (abstract judicial review). In addition to these competences, the BVerfG also rules “in the other instances provided for in this Basic Law” (Art. 93). It is the competent organ for declaring the forfeiture of basic rights (Art. 18), for cases of impeachment of federal judges (Art. 98) and of the federal president (Art. 61). Its function as a guardian of the Constitution perhaps finds its most evident expression in Art. 21 according to which the BVerfG shall rule on the question of the unconstitutionality of political parties.

The Federal System and the Division of Powers

The federation established after reunification in 1990 consists of 16 *Länder*, and each of them has its own constitution upon which the state institutions are based. Although both the *Bund* and the *Länder* are vested with the three branches of public power, these are not separate and distinct from each other. On the contrary, Germany’s system of cooperative federalism gives a significant example of what Fritz Scharpf termed *Politikverflechtung* (Scharpf 2009), referring to the complex interrelationship, interdependencies, and overlappings between the competences of the federation and the states. The Federalism Reform I of 2006 aims to disentangle these interdependencies, on the one hand by more precisely delimiting the allocation of legislative competences between the federal and the state level and on the other by reducing the risk of blocking situations which can potentially arise during the legislative process because of a divergence of majorities between *Bundestag* (Federal Diet) and *Bundesrat* (Federal Council). The latter consists of at least three and at the most six members of every *Land* government and has the ability to block federal legislation whenever it affects the interests of the *Länder*. In that case, the Grundgesetz requires the *Bundesrat*’s consent, and the latter has an absolute veto which cannot be overridden by an equivalent vote of the *Bundestag* (Art. 77). In order to decrease the *Bundesrat*’s possibility to block federal lawmaking, the federalism reform has significantly reduced the percentage of laws requiring its consent. Besides that, it profoundly altered the rules concerning the division of legislative competences. While the previous so-called “framework” legislation was abolished, both the matters of the federation’s exclusive (Arts. 71, 73) and concurrent (Art. 72) legislation were expanded.

The strong interconnection between federal and state level is at its greatest within the administration of justice. The courts of first and second instance (*Amtsgerichte*, *Landgerichte*, and *Oberlandesgerichte*) are state courts, whereas only the highest courts are established at the

federal level. Hence, there is a hierarchical division between the federal level and the *Länder*, and the federal courts do only control questions of legality. In addition to decentralization, there is also a high degree of specialization within the German court system. There are five different judicial branches – the ordinary, administrative, financial, labor, and social jurisdiction – with respective federal courts (*Bundesgerichte*) at their head which are scattered in different cities throughout Germany.

The German Civil Code and Private Law Society

The significance and importance of private law is emphasized by the ordoliberal concept of a Private Law Society (Böhm 1966), according to which the French Revolution marks the moment in which public order ceases to be the core governance mechanism in a hierarchically organized society, and consensus and private transactions become the main instruments for governing most parts of social life. However, since economic freedom, according to ordoliberal thinking, does only exist through order – it is an “ordered freedom” (Bonefeld 2012) – the new society, characterized by the equality of its members, party autonomy, freedom of contract, and freedom of competition, needs a strong state, called to assure the orderly conduct of self-interested entrepreneurs.

The German Civil Code of 1896 (*Bürgerliches Gesetzbuch* – BGB), which came into force on 1 January 1900 after 20 years of work, clearly reflects the core elements of a Private Law Society. The principle of freedom of contract, though it is nowhere expressly proclaimed, dominates the law of obligations and the idea that contracting parties are formally free and equal implicates that contracts thus formed must be adhered to in all cases. The typical citizen for the BGB is the *homo oeconomicus*, a person “who can be expected to have business experience and sound judgement, capable of succeeding in a bourgeois society with freedom of contract, freedom of establishment and freedom of competition” (Zweigert and Kötz 1994). Whenever the content of a contract was the

result of a bargaining process, the former was considered to be fair – it was the contractual mechanism itself that was said to guarantee the correctness of its outcome (Schmidt-Rimpler 1941). Put succinctly, the bargaining process between the parties was seen as “the epitome of fairness” (Markesinis et al. 2006), and the parties were considered to be the best guarantors of their respective rights. Thus, the idea that individuals are free to engage in private transactions as they see fit only finds limits in the case of the violation of statutory prohibitions (§ 134), *bonos mores*, or in those cases in which one party has exploited the plight, inexperience, or lack of judgment of the other (§ 138), whereas the draftsmen expressly rejected the doctrine of *laesio enormis*, holding that the idea of a *iustum pretium* did not conform to the idea of freedom of contract.

Severe criticism was expressed by those who argued against the dominance of laissez-faire concepts in favor of a more solidaristic approach, calling for the limitation of freedom of contract, which was accused of favoring only the propertied classes while suppressing the socially weaker ones (Anton Menger). Nonetheless, at the end, only a few “drops of socialist oil” (Otto von Gierke) were added to the soulless individualism of the Code. Party autonomy should not be considerably restricted, neither by means of statutory nor judge-made law. In fact, the role that the few open-textured general clauses inserted into the BGB should once have played was a role the drafting fathers had not counted on.

The BGB is divided into five books, each of which is devoted to a different subject, with a complicated system of cross-referencing between them. This applies especially to the first book, the so-called General Part (*Allgemeiner Teil*) which contains certain basic institutions – such as the provisions concerning natural and legal persons (including the concepts of consumer (§ 13) and business (§ 14) which were introduced in 2000 by a statute implementing various EEC consumer directives), juristic entities and foundations, and general rules about legal acts (*Rechtsgeschäfte*) – that have an effect on all the other four books (*Law of Obligations*, *Law of Property*, *Family Law*, and *Law of Succession*).

In particular, the provisions regarding legal acts – an artificial concept which represents the leading topic of the *Allgemeiner Teil* – provide evidence of the BGB's abstract conceptual calculus. The fundamental component of a *Rechtsgeschäft* is the declaration of intent, and this is why it does not only include “normal” types of contract, such as sale or lease and the so-called real contracts necessary to create or transfer real rights over another's property, but also the contract of family law such as marriage, as well as unilateral acts such as that of making a will (Zweigert and Kötz 1994).

In its concepts and its language, the BGB is the child of the abstract conceptualism of the Pandectist school. It does not deal with particular cases in a concrete manner, but adopts an extremely abstract, logical, and accurate legal jargon which is admired for its rigor of thought and precision, but criticized because of its lack of comprehensibility, especially for the ordinary citizen.

The BGB During the Twentieth Century

The question immediately arising in this context is how a Code which was said to be more “the cadence of the Nineteenth than the upbeat to the Twentieth Century” (Radbruch), thus doing no more than prudently summing up the past rather than boldly anticipating the future (Zitelmann 1900), could have survived till this day, transiting the German Empire, the Weimar Republic, Nazi Germany, two world wars, and German reunification without being subjected to fundamental revision; a Code which was described and criticized as conceptualist, libertarian, unsocial and individualistic, and unaware of the changing economic and social climate in the late nineteenth century.

The few drops of socialist oil inserted into the BGB indeed soon proved to be insufficient, in particular in the field of labor law. Already during the Weimar Republic, it became clear that the existing regulation was inadequate and incomplete and that legislative reforms were necessary in order to better protect dependent workers by means of

provisions concerning security of employment, worker participation, and minimum rates of pay (Zweigert and Kötz 1994). Thus, labor law for the most part developed outside the Code. But also in other areas of law, such as the law of housing, the need to take more account of the social needs of the time and to better protect the economically weaker parties in society led to a considerable increase of legislation outside the BGB; only since the 1960s parts of it have been gradually incorporated into the Code.

In certain cases, even the Code itself proved to be a useful instrument for coping with the changing social circumstances. In the aftermath of World War I, in a period of great instability, a sheet anchor to approach the arising great social and economic problems was represented by the general clauses inserted in the BGB. In particular § 242, which states that the performance of a contract has to be according to the requirements of good faith (*Treu und Glauben*), was envisaged by the judiciary as a possible loophole in order to afford the revaluation of debts, which proved necessary in consequence of the staggering hyperinflation of the early 1920s. Since currency laws explicitly established the nominalistic principle *Mark ist gleich Mark* (a paper Mark repaid during the inflation is equal to a gold Mark invested before inflation) and government rejected revaluation, it was left to the judiciary to find a solution for the constantly growing problem of the inflation effects on monetary relations. Although the legislator had never intended the principle of good faith to be used in this manner, in 1923, the *Reichsgericht* used it to request a revision of monetary obligations owed under contracts (RGZ 107, 78).

The significance and importance of the general clauses as a means which allows the courts to keep the Code up to date have also emerged in other areas. To cite just one example, in the context of standard terms of contract whose proliferation was the aftereffect of the Industrial Revolution at the end of the nineteenth century, the general clauses (especially § 242) turned out to be the decisive instrument in order to efficiently control the increasing number of cases dealing with standard terms. Many of the rules developed by the judiciary

in the course of time eventually turned into statutory form within the Act on General Conditions of Business of 1977 (*Gesetz zur Regelung der Allgemeinen Geschäftsbedingungen – AGBG*) whose provisions were partly inserted into the second book of the BGB in the course of the 2002 Act Modernizing the Law of Obligations (for details, see below).

However, the downside of open-textured principles with no clearly defined content became evident during the Nazi regime when the arbitrary misuse in particular of the principles of good faith and good morals, reinterpreted by the judges in order to direct the law in a way which served their nationalist ideology, led to the reassessment of a whole legal order by means of interpretation, resulting in the phenomenon of an *entartetes Recht* (Rüthers 1989), a “degenerated law,” entirely based on the National Socialist *Weltanschauung*. Though the Nazis had initially warned against the general clauses, there was now a real proliferation of undetermined terms in a number of new measures and special laws in order to serve as “entry points” for their ideology. Even more, the *Führer* principle and the *völkische Rechtsidee* (the popular notion of the law) according to which law was no longer perceived in terms of the rights of the individual but as the rights of the people as determined by the state became supra-positive and preexisting principles able to limit the existing written law. Doctrinal rationality and legal certainty got completely lost (Stolleis 1998). The plans of the Academy of German Law to create a *Volksgesetzbuch*, a “people’s Code,” in order to replace the BGB, however, did not progress beyond the draft.

The BGB initially continued to be in force in both parts of Germany also after World War II. In the GDR, it was gradually replaced only some years after the construction of the Wall. On 1 April 1966, the Family Code led to the abrogation of the fourth book of the BGB; 10 years later, the BGB was entirely replaced by the *Zivilgesetzbuch* (ZGB) which entered into force on 1 January 1976 (and was replaced by the BGB in 1990). In the FRG, the entering into force of the *Grundgesetz* in 1949 has fundamentally inspired the evolution of German Private Law, through to its constitutionalization. In this

context, again, the role of the general clauses was – and continues to be – a fundamental one. Today, the general clauses are commonly described as “gateways” (*Einfallstore*) for the Basic Law’s value judgments (*Wertesystem*) in the realm of private law. In other words, the fundamental rights enshrined in the *Grundgesetz* do not have any direct effect on private law relationships, but it is the courts’ duty to take them into account while interpreting the general clauses of the BGB in order to provide them with more concrete content. The idea of the fundamental rights’ *mittelbare Drittwirkung* (indirect horizontal effect) was laid down for the first time in the famous Lütth Case of 1958 (7 BVerfGE 198), in which the BVerfG stated that the Basic Law contains an “objective order of values” (*objektive Werteordnung*) which must be looked upon as a fundamental constitutional decision affecting all areas of law, including private law.

The theory of the “radiating effect” (*Ausstrahlungswirkung*) of the basic rights in relations governed by private law has played a fundamental role in all subsequent court decisions on the subject and has given rise to a substantive body of case law developed by the courts. That it has also led to far-reaching consequences within the law of contract becomes particularly clear in the context of the famous *Bürgschaft* Case of 1993 in which the Federal Constitutional Court obliged civil courts to intervene on the basis of the general clauses of good morals and good faith – using the principles of party autonomy (Art. 2) and the social state (Art. 20) enshrined in the Constitution as interpretative guidelines – in a case in which the “structural imbalance of bargaining power” had led to an “exceptionally burdensome contract” for the weaker party (89 BVerfGE 214 (1993)).

The Europeanization of the BGB: Legal Developments in Private Law in the Twenty-First Century

The Act Modernizing the Law of Obligations (*Schuldrechtsmodernisierungsgesetz*) of 1 January 2002 is considered to be one of the most sweeping reforms of the BGB since it was enacted. The necessity to transpose several EC Directives,

among which the Consumer Sales Directive of 1999, was used as an occasion to realize the often called for fundamental reform of the law of obligations (the so-called *grobe Lösung*). This explains why most parts of the new provisions go back to and are largely based on reform proposals which had never progressed beyond the draft stage, prepared by a commission of leading academics and practicing lawyers in the early 1990s already. Because of its extremely short legislative process, the modernizing reform was heavily criticized by those who had argued in favor of a *kleine Lösung*, i.e., a legislation transforming only the Consumer Sales Directive without totally reforming the whole law of obligations. The Modernizing Act not only affected key elements of the general law of obligations and the contracts of the sale of goods, but also led to the integration into the BGB of many of the special statutes concerning consumer rights which over the years had developed outside the BGB and are the result of a transposition of EC Directives in this field. Since central parts of the new law of obligations have transposed European Directives, the reform is largely understood as a Europeanization of the BGB (Schulze and Schulte-Nölke 2001); the reform has thus also aimed to turn the BGB into a model in the context of the harmonization of European contract law. Having said that, the highly visible influence of the BGB within the framework of the Draft Common Frame of Reference (DCFR) is certainly also due to the leading role of German academics within the Joint Network on European Private Law entrusted with its elaboration.

The influence of EC/EU law has constantly grown over the last years, in particular in the field of consumer protection law which is increasingly inspired by the so-called information model. In German literature, the instrumentalization of the consumer as a means to promote the internal market on the basis of a model of procedural justice – more precisely of the idea that a sufficiently informed consumer is able to reach a completely rational decision – is said to have brought about a “dematerialization” and “re-formalization” of (national) consumer protection law (Micklitz 2012). The most recent example of this tendency is represented by the Consumer Rights Directive 2011/83/EU which was

implemented in June 2013 by means of an amendment of the law of obligations.

Legal Education and Legal Professions: The German Construct of *Einheitsjurist*

The particularity and main characteristic of the German system of legal education is the fact that it is embedded in the model of a “uniform jurist,” the so-called *Einheitsjurist*. The admission to all legal professions requires exactly the same formal qualification, so education is identical for everyone, regardless of the legal profession to be adopted in the future. Since federal legislation, i.e., the German statute of judges (*Deutsches Richtergesetz – DRiG*), *only* lays down general provisions and standards in the field of university education and practical training, each *Land* disposes of more detailed regulations. This has given rise to quite different rules – mainly related to procedural aspects of examination – in the 16 *Länder* (Keilmann 2006).

The legal education system is a two-phase one. It is a state-oriented and judge-centered bureaucratic model with traditionally great emphasis on the technical skills needed in the judiciary which has only been slightly reduced in recent times. It has its roots in the Prussian system of legal education and justice which already at the beginning of the eighteenth century was characterized by a state-controlled meritocratic selection for entry into the public administration on the basis of state examinations.

University studies in law end with an examination which today is called “first examination” (*erste Prüfung*) and no longer “first state exam” (*Erstes Staatsexamen*) because it is no longer entirely organized by the *Länder’s* Court of Appeals and the state offices for the Law Examinations (*Landesjustizprüfungsämter*). The modification brought about by the Act on the Reform of Legal Education of 2002 is an aggregate final exam mark, composed of an examination conducted by the law faculties in certain areas of specialization which students can choose (*universitäre Schwerpunktbereichsprüfung*) and a state exam which covers compulsory subjects (*staatliche Pflichtfachprüfung*). The former

represents 30, the latter 70 % of the final mark. Low average marks, high failure rates, and the assumption among students that university courses do not suitably prepare them for the exam have caused a run on the expensive service of private law teachers, the so-called *Repetitoren*. This dualism of abstract metatheory and practical legal training, which goes back to ideas diffused by Wilhelm von Humboldt at the beginning of the nineteenth century (Keilmann 2006), is heavily criticized but does not seem to draw to a close. Today, even the law faculties themselves offer special preparation classes in order to keep up with the private *Repetitoren* (Korioth 2006). The fact that privatization has affected the legal education system is also proved by the presence of the Bucerius Law School, the first and up to now the only private law school in Germany which was founded in 2000 and is located in Hamburg.

Legal studies are followed by a biennial practical training (*Referendariat* or *Vorbereitungsdienst*), organized and paid for by the *Land* in which it is undertaken. This period, during which the *Referendare* are instructed in various areas (civil courts, criminal courts or public prosecutor's office, public administration, and law firms) in order to obtain preparation for the main legal professions, ends with the "second state examination" (*zweite Staatsprüfung*). After successfully passing it – candidates only have two attempts, but failure rates are less than 15 % – the young lawyer is called *Assessor* or *Volljurist* (fully qualified jurist) and, having obtained "the qualification for the office of a judge" (§ 5 DRiG), he/she is theoretically qualified for any legal profession. That means, for example, that there is no additional bar exam, and to practice as a *Rechtsanwalt* (attorney), only a formal admission is required. However, access to a legal career is strongly determined by examination grades. Since for a career in the judiciary or civil service it is a precondition to achieve a top mark in the second state examination (the so-called *Prädikatsnote*) – a criteria which is fulfilled by fewer than 10 % of the aspirants – the overwhelming majority work as attorneys; only a small percentage has the option of becoming a judge (*Richter*), a public prosecutor (*Staatsanwalt*), a notary (*Notar*), or undertaking an

academic career. As a response to this reality, the Reform of 2002 has extended the practical training during the *Referendariat* at a law firm from 3 to a minimum of 9 and a maximum of 13 months.

Attorneys who have practiced as lawyers for at least 3 years can specialize in a particular field of expertise in order to attain the title of *Fachanwalt*. In a few *Länder*, attorneys can also become the so-called *Anwaltsnotare* (lawyer notaries) who combine the profession of an attorney with that of a notary on the condition that they have practiced the forensic profession for 5 years. They are the second major type of notaries beside the so-called *Nurnotare* (fulltime notaries). Both groups have to pass a third exam, the so-called *notarielle Fachprüfung*. Due to the limited number of posts available, competition is hard, and the door to this profession is only open to the top law graduates.

As seen above, the judiciary follows a separate career path: it is immediately entered after the second state examination by those who have achieved excellent final marks, and only rarely does a practicing lawyer transfer to become a judge. The initial appointment to a local or a regional court will only be for a certain period, usually for 3 years, during which the candidate is a *Richter auf Probe*, i.e., his employment status is "on probation." A *Richter auf Lebenszeit*, a lifetime judge, can be promoted to higher regional courts on the condition that he has worked for at least 10 years in the courts of first instance. Whereas the initial appointments and this kind of promotion are made by the state's ministers of justice, appointments to the five federal courts involve the competent Federal Minister and a so-called *Richterwahlausschuss*, a committee for the selection of judges which consists of the competent *Land* ministers and an equal number of members elected by the *Bundestag*.

Gibbard-Satterthwaite Theorem

Pierre Bernhard¹ and Marc Deschamps²

Definition

One seminal question in social choice theory was: is it possible to find a social choice function such that each agent is always better off when telling the truth concerning his preferences no matter what the others report? In other words, can we find a strategy-proof voting rule? With at least three alternatives and two voters, the answer is clearly no under a very general framework, as was proved independently by Allan Gibbard and Mark Satterthwaite. Since then, the Gibbard-Satterthwaite theorem is at the core of social choice theory, game theory, and mechanism design.

Introduction

Since K. Arrow’s 1951 analysis, which marks the revival of the theory of social choice, economists investigate from an axiomatic point of view the aggregation of individual preferences in order to obtain a social welfare function (i.e., a complete and transitive ranking based on the individual preferences) or a social choice function (i.e., one alternative from the individual preferences). Such questions concern huge domains of human beings, for example, the family’s choice of the walls color in the living room, the choice of the Palme d’Or winner by the jury of the Cannes International Film Festival, or the vote for the President of the European Commission. Thus, in

addition to his (im)possibility theorem, K. Arrow has initiated a new domain in economic analysis.

Since then, the question of the strategic behavior of individuals during an election was raised again on several levels. Indeed for a very long time, since we find, for example, a letter from Pline the Younger in Roman Antiquity, the question of manipulation had attracted attention. Whether playing on who will be a voter, who can be a candidate, the choice of the voting rule, abstention, beliefs about preferences or preferences expressed during the vote, the idea that at least one individual can do a manipulation to his advantage has interested and concerned many thinkers.

Concerning this last form of manipulation, it was historically mentioned at least seven times before the Gibbard-Satterthwaite theorem (an expression first used by (Schmeidler and Sonnenschein 1978)). First, a story probably apocryphal tells that Borda responded to one of his critics who pointed out that his method was manipulable that it was intended for use by honest people. There is also a reference to this question in Ch. Dodgson (alias Lewis Carroll), who said in a specific voting system, “This voting principle makes an election more of a skill game than real test of voters’ wishes” (see Black (1958)). In the modern period, Black (1948) discusses the link between unimodal preferences and strategic votes, while (Arrow 1951, p. 7) explicitly states that he will not deal with this issue even though he later returns to it in a footnote [footnote 8, pp. 80–81]. Arrow’s general analysis, however, will lead (Vickrey 1960, pp. 517–519) to conjecture that immunity to strategic manipulation is logically equivalent to the association of the axiom of independence of irrelevant alternatives and that of positive association. Finally, it will be R. Farquharson in his 1958 doctoral dissertation, published in 1969, (Farquharson 1969), who will introduce the distinction between “sophisticated strategy” and “sincere strategy,” and then in an article with M. Dummett in 1961 when they make the conjecture: “It seems unlikely that there is any voting procedure in which it can never be advantageous for any voter to vote ‘strategically,’ i.e., non sincerely” (Dummett and Farquharson 1961,

p. 34). In an interview given in 2006 to R. Fara and M. Salles, M. Dummett confesses that he felt at this time that proving this conjecture would be extremely difficult and that is why they did not try the demonstration. We refer the reader to (Barberà 2010) for more details on this historical part.

Thus, for more than 20 years after (Arrow 1951), all scholars of social choice theory seem to have been convinced that the question of the manipulation of preferences by an individual (i.e., the fact that he does not express his true preferences in order to lead to a social choice that satisfies him better than would have been obtained if he had been honest) was an important question, easy to explain, but very difficult to prove.

As an illustration of this question of the manipulation of preferences by an individual, we can give the following example (from (Feldman 1979, p. 459)):

Imagine a committee made up of 21 members each having one vote and whose actual preferences presented in descending order can be broken down into three groups.

Type 1	Type 2	Type 3
A	B	C
B	C	B
C	A	A
10 voters	9 voters	2 voters

In a majority election where voters indicate their real preferences, A gets 10 votes, B gets 9 votes, and C gets 2 votes; this leads to the election of A. However, if anticipating this result, the voters in group 3 manipulate their preferences and vote for B, this will lead to 10 voters for A and 11 voters for B and so B will be elected. This strategic choice of the voters of the group 3 allows them to obtain a more favorable result than they would have obtained if they had voted sincerely. **I**

Therefore, a question immediately comes to mind: is it possible to imagine a social choice function such that each individual, regardless of the others’ choices, is always better off by expressing his true preferences? In other words, is there a social choice function such that always telling the truth is a strictly dominant strategy for

each individual? The answer to this question was independently given by the philosopher Allan Gibbard (1973) and the economist Mark Satterthwaite (1975) (work summarizing part of his doctoral dissertation defended in 1973) and it is unfortunately negative. What we call since the Gibbard-Satterthwaite theorem can be broadly stated as follows: *it is not possible to find a social choice function that is both nonmanipulable and nontrivial.*

This last term deserves an explanation. By a trivial function we mean one of the following solutions (or a solution equivalent to it): 1/ a dictatorship (i.e., all the power of decision resides with a single individual and he has no indifferent choice), 2/ the permanent choice of an alternative whatever the preferences expressed by the individuals are (which could, for example, correspond to a tradition which would be imposed in all circumstances), 3/ the perfect unanimity of all the voters (which in fact means having perfect clones and therefore no diversity in the preferences), or 4/ the majority between two alternatives only, whatever the number of other alternatives existing and the votes that are expressed for them. Thus, if all individuals know their preferences and those of others and that there are at least three possible alternatives and at least two voters, there is no social choice function that implies that each individual always has an interest in expressing his or her real preferences. We thus find here the conditions of Arrow's theorem and the same conclusion since when there are only two alternatives, majority voting is at the same time a nondictatorial and nonmanipulable social choice function.

Since then, the Gibbard-Satterthwaite theorem has been considered, along with Arrow's theorem, as one of the two most famous results of social choice theory and has led to a very large literature in this field. It also plays a crucial role in public economics and in the theory of incentive mechanisms, which can be broadly seen as a social engineering approach of finding the rules to achieve a specific outcome from agents interacting strategically and having private information (see Börger (2015)). Indeed, because of

this theorem, the incentives of individuals must be considered as relevant constraints in the design of any mechanism.

Gibbard-Satterthwaite Theorem

Many proofs of this theorem have been proposed and it is possible to consider that they take one of the following four paths: 1/ that used by A. Gibbard and which uses Arrow's theorem, 2/ that used by M. Satterthwaite thanks to a combinatorial argument and recurrences on the number of individuals and alternatives, 3/ that considering this theorem as the consequence of the fact that nonmanipulability requires strong monotony (see Moulin (1988)), and 4/ that developed by S. Barberá and his coauthors using the concept of pivotal agents. For a first presentation of the question of manipulation, we refer to Feldman (1979) and for a review of this literature we refer to Sprumont (1995) and Barberá (2010).

Following Gibbard's approach, we will prove the Gibbard-Satterthwaite theorem as a corollary of Arrow's (im)possibility theorem. The presentation we retain will distinguish the formal setup, the links between the two theorems, the proof of the Gibbard-Satterthwaite theorem, and that Arrow's theorem in turn can be seen as a corollary if we directly prove the Gibbard-Satterthwaite theorem.

Formal Set-up

Let $\mathcal{A} = \{a, b, \dots\}$ be a set of three or more alternatives. Let P be the set of linear orders over $\mathcal{A}$, and $\mathcal{P} = P^n$. An element $\Pi = (P_1, P_2, \dots, P_n) \in \mathcal{P}$ is called a *profile*, and the P_i the *individual preferences*. The order in P_i is denoted $a \succ_i b$ for "player i prefers a to b ." We further define

Definition 1

The domination set of $a \in \mathcal{A}$ in P_i

$$\mathcal{D}(a, P_i) = \{x \in \mathcal{A} \mid a \succ_i x\}$$

Moreover, for $\Pi = (P_1, \dots, P_n)$, $\mathcal{D}(a, \Pi)$ stands for the product set of the $\mathcal{D}(a, P_i)$. Thus,

let $\Pi' = (P'_1, \dots, P'_n)$ be another profile, the notation $\mathcal{D}(a, \Pi') \supseteq \mathcal{D}(a, \Pi)$ means: $\forall i \in \{1, \dots, n\}$, $\mathcal{D}(a, P'_i) \supseteq \mathcal{D}(a, P_i)$.

Definition 2

- A social welfare function (or SWF) is an application $f: \mathcal{P} \rightarrow P$.
- A social choice function (or SCF) is an application $F: \mathcal{P} \rightarrow A$.

The order relation in $f(\Pi)$ will be denoted $a > b$ or, if needed $a >_{f(\Pi)} b$. We need to define the following properties of SWF or SCF:

Definition 3

- The SWF f is Pareto efficient (or satisfies the unanimity rule) if

$$[\forall i \leq n, a \succ_i b] \Rightarrow a > b.$$

- The SCF F is Pareto efficient, (or satisfies the unanimity rule) if whenever an alternative $a \in A$ is the most preferred alternative in all individual preferences, it results that $F(\Pi) = a$.
- The SWF f is independent of irrelevant alternatives (IIA) if, for any a and b in A , the relative ranking of a and b in $f(\Pi)$ only depends on their relative rankings in the P_i , irrespective of the rankings of other alternatives.
- The SCF F is monotonic if, given two profiles Π and Π' ,

$$[F(\Pi) = a \text{ and } \mathcal{D}(a, \Pi') \supseteq \mathcal{D}(a, \Pi)] \Rightarrow F(\Pi') = a.$$

- The SCF F is strategy-proof if, when Π and Π' differ only in changing P_i into P'_i , it results that either $F(\Pi) = F(\Pi')$ or $F(\Pi) \succ_i F(\Pi')$.
- The SWF f is called dictatorial if there exists a player k such that, $\forall \Pi \in \mathcal{P}$, $f(\Pi) = P_k$. (The social preferences are always player k ' preferences.)

- The SCF F is called dictatorial if there exists a player k such that, $\forall \Pi \in \mathcal{P}$, $\forall x \neq F(\Pi)$, $F(\Pi) \succ_k x$. ($F(\Pi)$ is player k 's most preferred alternative.)

Arrow and Gibbard-Satterthwaite Theorems

Theorem 1 (Arrow) If a SWF is Pareto efficient and IIA, then it is dictatorial.

Theorem 2 (Gibbard-Satterthwaite) If a SCF is strategy-proof and onto (i.e., its range is all of A : $\forall a \in A, \exists \Pi \in \mathcal{P}$ such that $F(\Pi) = a$), it is dictatorial.

Lemma 1 (Muller and Satterthwaite) If a SCF is strategy-proof and onto, it is monotonic and Pareto efficient.

Proof Let Π and Π' be two profiles, $F(\Pi) = a$, $\mathcal{D}(a, \Pi') \supseteq \mathcal{D}(a, \Pi)$, but assume that $F(\Pi') \neq a$. Make the change from Π to Π' one player at a time in numeric order. Denote by Π_k the profile obtained after changing P_k to P'_k . (And $\Pi_0 = \Pi$). At some point, we have that $F(\Pi_{i-1}) = a \neq b = F(\Pi_i)$. By strategy-proofness, it follows that $a \succ_i b$ in P_i while $b \succ_i a$ in P' . But by hypothesis, if $a \succ_i b$ in P_i it is a fortiori true in Π' , a contradiction. Therefore, the SCF is monotonic.

Because F is assumed to be an onto function, for any given $a \in A$, there exists a profile Π such that $F(\Pi) = a$. Build Π' by moving a at the top of the preferences of all players. By monotonicity, it still holds that $F(\Pi') = a$. Now, get Π'' by shuffling at will the preferences of all players below a , leaving a at their top position. Because of the definition of monotonicity, and specifically its IIA-like character, it still holds that $F(\Pi'') = a$. Therefore, the SCF is Pareto efficient. **I**

Proof of the Gibbard-Satterthwaite Theorem

This note is devoted to the proof of the Gibbard-Satterthwaite theorem viewed as a corollary of Arrow's theorem. We assume therefore that the latter is known. Given the above Lemma 1, we need to prove

Lemma 2 *If a SCF is Pareto efficient and monotonic, it is dictatorial.*

Our method of proof will be as follows: we assume that a SCF F is known which is Pareto efficient and monotonic. From it we construct a SWF f which we show to be Pareto efficient and IIA, therefore dictatorial, which will imply that F is dictatorial.

Let F be a SCF. Given a profile Π , our social ordering $f(\Pi)$ is built via the following algorithm:

Algorithm

- Let $\Pi_1 = \Pi$.
- For i ranging from 1 to n , do:
 - define $a_i = F(\Pi_i)$,
 - define Π_{i+1} by moving a_i at the bottom of all individual preferences in Π_i .
- Define $f(\Pi)$ as: for all $i \in \{1, \dots, n-1\}$, $a_i >_{f(\Pi)} a_{i+1}$.

Proposition 1 *If the SWF F is Pareto efficient and monotonic, the above algorithm produces a linear order on $\mathcal{A}$.*

Proof What we need to prove is that all elements of $\mathcal{A}$ will be ranked, i.e., that for all $i \in \{1, \dots, n\}$, and for all $j < i$, $a_i \neq a_j$.

Let first $i < n$. Therefore, not all alternatives have been numbered as one of the a_k . Define Π'_i as follows: Take an alternative b which has not yet been ranked. Raise it at the top of all individual preferences. This does not change the domination sets: $\mathcal{D}(a_j, \Pi'_i) = \mathcal{D}(a_j, \Pi_i)$ since in Π_i , all the alternatives that have already been selected in the algorithm, including a_j (remember that $j < i$), are stacked at the bottom of all individual preferences. Therefore, by monotonicity, if $F(\Pi_i) = a_j$, it also holds that $F(\Pi'_i) = a_j$. But by Pareto efficiency, $F(\Pi'_i) = b$, a contradiction.

Finally, in Π_n , $n-1$ different alternatives have been placed at the bottom of all individual preferences; thus, the same and last alternative is alone at the top of all and is therefore selected by F by Pareto efficiency.

The following propositions end our proof:

Proposition 2 *If the SCF F is Pareto efficient and monotonic, the SWF defined by the algorithm is*

1. *Pareto efficient*
2. *Independent of irrelevant alternatives (IIA), and therefore dictatorial by Arrow's theorem*

Proof

1. Let $a, b \in \mathcal{A}$, and assume that in Π , $\forall i \in \{1, \dots, n\}$, $a \succ_i b$. Assume that at some step of our algorithm, $F(\Pi_i) = b$, but a has not yet been chosen. In Π_i , raise alternative a at the top of all individual preferences. This does not change the domination sets of b in any individual preferences. Therefore, F should still select b . But by Pareto optimality, it should select a . A contradiction.
2. Let $i < j$ and therefore by our algorithm, $a_i >_{f(\Pi)} a_j$. In Π , move another alternative b in some individual preferences, call the new profile Π' . We claim that in the order created by our algorithm applied to Π' , it still holds that $a_i > a_j$.

Assume that $F(\Pi') = b$. Then at step 2, b is brought at the bottom of all individual preferences, and, as compared to profile Π , the domination sets of a_1 have been enlarged or kept unchanged for all individual preferences. Therefore, $F(\Pi'_2) = a_1$. If $b \neq a_2$, at step 2, for the same reason a_2 will be selected, and so forth until the end of the algorithm. Therefore, we will still select a_i before a_j .

Assume $F(\Pi') = c \neq b$, and assume $c \neq a_1$. This is possible only if in one individual preferences at least, b has been moved from below a_1 to above it. In these individual preferences only, bring b back below a_1 . Call this profile Π'' . $\mathcal{D}(a_1, \Pi'') \supseteq \mathcal{D}(a_1, \Pi)$. Therefore $F(\Pi'') = a_1$. But in going from Π' to Π'' , b has only been moved down in some individual preferences. Therefore $\mathcal{D}(c, \Pi'') \supseteq \mathcal{D}(c, \Pi')$. Therefore, $F(\Pi'') = c$. Hence, $a_1 = c$ contrary to the hypothesis. Hence, $F(\Pi') = a_1$.

Repeat this argument at each step before b is selected, and once this happens, repeat the

previous argument. It follows that, except for b , all other alternatives are chosen in the same order as for Π . **I**

It follows that, by Arrow's theorem, f is dictatorial. There is a player k such that for all Π , $f(\Pi) = P_k$, and in particular $F(\Pi)$ is player k 's preferred alternative. And this proves Lemma 2, and consequently the Gibbard-Satterthwaite theorem. **I**

Complement: Arrow's Theorem as a Corollary of Gibbard Satterthwaite

It can also be shown that if the Gibbard-Satterthwaite theorem has been proved directly, Arrow's theorem is an easy corollary, thus establishing the equivalence between the two results. The process is symmetrical from the above one, deriving a SCF from a Pareto efficient and IIA SWF by simply picking the top alternative in the social preferences and showing that it is onto and strategy-proof.

We might also mention that Lemma 1 has an easy reciprocal.

Conclusion

Since its demonstration, the Gibbard-Satterthwaite theorem has generated a huge literature on the question of the manipulation of preferences, distinguishing, in particular, the cases where the social choice function is manipulable by an individual from the case where it is manipulable by a coalition of individuals. It has also been extended to take into account set-valued (Duggan and Schwartz 2000) and nondeterministic choice functions (Gibbard 1977), that is, those where the result depends on the votes of individuals but also by chance. (Often both set-valued and non-deterministic.) Our framework requires that social choice function is onto. It has been proven since that the results hold as soon as the social choice function has at least three alternatives in its range.

In our opinion, three main ways of circumventing this theorem have been followed. The first is to restrict the preference domain (with functions defined on restricted sets of preference profiles, it is

possible to find social choice functions that are both nondictatorial and nonmanipulable, e.g., unimodal preferences *à la* Black). The second is to change the goal. Indeed, the framework in which the Gibbard-Satterthwaite theorem is situated is very strong since it seeks a social choice function for which telling the truth is a dominant strategy for each individual. The path followed by implementation theory is to simply ask that it be a Nash strategy, or a perfect subgame strategy, or a Bayesian Nash strategy, depending on the informational context of the individuals. Finally, more recently, a third way explains that this problem is real but may not be very important empirically. Indeed, besides the integrity, ignorance or stupidity of individuals that can prevent them from performing manipulations, the fact that a social choice function is manipulable does not imply that it will be manipulated. And since Bartholdi et al. (1989), economists consider that it may be empirically impossible for individuals to decide how to manipulate even when they have all the information to do so, as the problem may be NP-hard.

Global Warming

Alfred Endres

FernUniversität Hagen, Hagen, Germany

Abstract

This essay analyses global warming from the perspective of environmental economic theory: National activities to curb greenhouse gas emissions are public goods. It is well known that the expectations to arrive at a satisfactory provision of these kinds of goods by

uncoordinated decision-making are low. Nations try to overcome this dilemma by international treaty-making. However, economic analysis suggests that the genesis and persistence of international climate agreements are challenged by problems of national rationality and stability as well as by the leakage effect. On the other hand, economic analysis reveals some reasons for a more optimistic view. Among those are incentives to develop and introduce green technologies and incentives to adapt to changes in the world climate.

Introduction

Human economic activity is directed to produce commodities and services which are valued by people. Many of these goods are sold and bought in markets where consumers pay a market price to reimburse the production costs to the supplying firms and contribute to the profits of these firms. Jointly with these intended products of the economic activity, unwanted side products are generated, like waste and emissions into environmental media (e.g., air and water). The generation of these side products can be steered in terms of quantity and quality, but it is unavoidable in principle.

There are millions of different types of substances which are emitted into the environment as by-products of the productions process. A certain subset of these emissions constitutes the group of *greenhouse gases (GHG)*. Among this type of gases are carbon dioxide (CO₂), nitrous oxide (N₂O), chlorofluorocarbons (CFCs), methane (CH₄), and ozone (O₃). There is a broad consensus in the natural sciences that the emission of these greenhouse gases changes the atmospheric conditions around the globe to such an extent that the world climate is adversely affected. Particularly, increases in the stock of greenhouse gases in the atmosphere contribute to an increase of the average temperature on earth (*global warming*). This

is a phenomenon of fundamental concern in the society and for policy makers. It is also an important issue of research undertaken and policy advice given by economists. Climate change affects the living conditions of the people directly, and it also changes the conditions under which many commodities and services are produced (e.g., in agriculture and tourism).

From the perspective of sciences, climate change is an issue which has so many dimensions intertwined in a very complex way that it can only be dealt with using an interdisciplinary approach. Of course, in this interdisciplinary process of communication, collaborators from the social sciences (like economics) cannot really assess the quality of the research in the natural sciences. So economists usually take for granted what the mainstream of natural science research takes to be true. This is particularly so with regard to the quantitative effect that certain greenhouse gases have on the world climate and in terms of the effect that certain changes in the climate have on the living conditions on earth (e.g., sea level rise and increases in extremely adverse weather conditions).

There is a broad consensus in the world that global warming has anthropogenic origins and is extremely dangerous to human kind. Even though not each consequence of higher average temperature in the world is detrimental, the aggregate effect appears to be a severe threat to the living conditions on earth. (A standard reference in this context is the *Stern Review*, Stern (2007), see also Stern (2015))

The problem is very well known among the political leaders of the world and to the people, at least in the economically developed countries. (The beginning of the international efforts to protect the climate was marked by the *Earth Summit* in Rio de Janeiro in 1992.) On the other hand, there is no progress in terms of a reduction in the globally aggregated quantity of GHG emissions. In the public media, “uninterested and incompetent politicians” are often held responsible for this lack of progress. However, economic analysis shows that the climate problem is very hard to solve even if we assume that the involved governmental decision-makers are competent and seek to

serve the interest of the people they represent. This is due to an adverse incentive structure that impedes an international consensus on an effective climate change policy.

An Economic Perspective of Global Warming

Greenhouse gases are to be distinguished from most other pollutants in that they do not have a regionally specific dose–response profile. Instead, they are global in the sense that after their emission they disperse homogeneously around the atmosphere of the earth. Particularly, the regional structure of these pollutants’ generation is irrelevant for their effect on the global climate. Changes in the world climate are induced by the aggregate effect of GHG emissions and, particularly, by the stock of greenhouse gases in the atmosphere that is accumulated by the emission flow generated in each consecutive period of time. Thereby, global pollutants have properties that come very close to the economics textbook stylization of a “pure public good (bad),” which is an important issue in *microeconomic theory*, *public finance*, and *environmental economics*. The problems that arise when governments strive to agree upon curbing GHG emissions to a tolerable level can thereby be explained using insights from the economic theory of public goods.

Concerning greenhouse gases, each individual country is in a double role: On the one hand, the country is the generator of the problem emitting certain quantities of these gases. On the other hand, the country is the victim of its own activity suffering from the detrimental effect this activity has on the climate. However, since it is not a country’s specific climate which is under consideration here but the world climate, the country is not the only victim of its own activity. All other countries are also victimized by the pollution of the individual country under consideration. In terms of economic theory, each country generates an *internal effect* as well as an *external effect* by its GHG emissions. The problem arising here is that a government striving to maximize the welfare of the citizens that it represents designs a GHG

policy that takes the internal effect into account and ignores the external one.

The welfare effects of a country's GHG policy are two-fold. On the one hand, the national economy has (the citizens have) to bear the costs of the policy. This reduces national welfare. On the other hand, the country benefits from its own policy in that the GHG-reducing measures are advantageous in terms of the world climate. Therefore, the climate change damages the country under consideration suffers from are reduced. The national welfare effect of the national climate policy is maximized when this policy is designed to maximize the difference between the national benefits (reduction in national climate change damages) and national climate change costs. The quantity of GHG reduction for which the aforementioned difference is maximized is called the *equilibrium quantity* of emission reduction for the country under consideration. It is fundamental to note that this nationally optimally designed climate policy is drastically different from the design of a national climate policy which is optimal from the point of view of the world as a whole. From this global point of view, in order to characterize optimal national climate policy, the cost of this

policy has to be compared with the benefits of this policy aggregated across all the countries of the world (instead of the country under consideration only). The quantity of country i 's emission reduction which maximizes the difference between aggregate benefits and costs to country i is called the *globally optimal quantity* of i 's emission reduction.

In economics, it is a standard exercise to clarify and specify these thoughts using formal mathematical analysis or graphical visualization. In what follows, we turn to the latter Fig. 1.

In Fig. 1, the term B_i denotes the benefit, B , of GHG emission reduction in some country, i . X_i denotes the quantity of this reduction in the aforementioned country. The function $B_i(X_i)$ denotes these benefits as they depend upon the quantity of the pollutants reduced. It is assumed in this figure that this function is known to the decision-makers. In reality (and in more elaborate theoretical expositions), it is to be acknowledged that the extent of damages and the manner in which they systematically depend on the extent of emissions reduction is highly uncertain. There is an extensive literature dealing with this issue, which is ignored here. In the present context, the figure is
